TREATMENT OF CAUSALGIA

RESULTS OF INTRANEURAL INJECTION OF
60 PER CENT. ALCOHOL

DEAN LEWIS, M.D.

CHICAGO
AND

WESLEY GATEWOOD, M.D.
IOWA CITY

Causalgia is one of the most distressing complications or sequelae of peripheral nerve lesions. This syndrome, observed by Weir Mitchell during the Civil War, has as its predominant feature pain which is described as burning or throbbing in character and is often compared to the sensations produced by pin pricks, a red hot iron or an injury of the flesh. This pain, which never ceases, even at night, may be aggravated by any number of causes and finally becomes paroxysmal.

It is difficult to determine its frequency, for statistics concerning peripheral nerve lesions differ widely. This variation is probably due to differences of opinion regarding the type of case that should be regarded as causalgia. Varying degrees of pain are observed after peripheral nerve injuries, but only the intense paroxysmal type should be regarded as causalgia. Four cases of causalgia were noted among the 550 cases of peripheral nerve injuries which we observed at U. S. General Hospital No. 28. Three of these patients have been operated on and cured by intraneural injections of 60 per cent. alcohol. It is probable that the fourth patient, who is still under observation, will require this treatment.

Weir Mitchell believed the pain due to an ascending neuritis which might involve any injured nerve and gradually involve all the nerves of the extremity affected. It seems to have been demonstrated, however, as a result of surgical interference, that the median nerve is involved most frequently in causalgia affecting the upper extremity, and the internal popliteal in causalgia involving the lower extremity. When a lesion of the ulnar nerve is accompanied by intense pain, it is usually due to an associated lesion of the median nerve or to an injury of the brachial plexus affecting both ulnar and median nerves. Other nerves may be involved. In one of the cases observed by us pain persisted, although diminished in intensity, over the distribution of the long saphenous nerve after injection of the internal popliteal. The pain subsided completely after injection of the long saphenous nerve.

The pathology differs widely in different cases. Joyce has reported five cases, in one of which the

median nerve when freed from scar tissue appeared swollen and bluish gray, mottled with purple spots. A small neuroma, which was adherent to the biceps, was found on the nerve. In another patient who complained of severe pain in the foot when walking, sitting or lying down, but who had no paralysis or anesthesia, there was found on roentgenographic examination a small foreign body in the neighborhood of the sciatic nerve. When the operation was performed, the foreign body was found embedded in scar tissue just posterior to the nerve. Immediate and permanent relief of pain followed removal of the foreign body. Gosset found the median nerve only slightly affected in the operations performed by him to relieve causalgia affecting the hand. In one of the cases observed by us, the median and ulnar nerves were embedded in scar tissue, and the median nerve was definitely enlarged and indurated just above the antecubital fossa; in another, the internal popliteal nerve was surrounded by some adhesions which were not at all dense, and the long saphenous nerve, which was subsequently injected below the wound, appeared normal. In both of these cases, neurolysis had been previously performed but had given no relief. In the third case, the median nerve appeared injected and somewhat enlarged, but its consistency did not differ from that of a normal nerve.

REPORT OF CASES

CASE 1.—Median and ulnar nerve embedded in scar tissue in the lower third of left arm. Median nerve enlarged and indurated just above the antecubital fossa. Previous neurolysis without relief.

Private E. G., wounded at Château-Thierry, July 19, 1918, had been struck by a machine gun bullet in the left arm midway between the shoulder and the elbow. This produced a comminuted fracture of the humerus and a paralysis of the ulnar, median and musculospiral nerves. He gradually recovered from the musculospiral paralysis, but about ten days after the wound was received he experienced a burning pain in the hand which became paroxysmal in character. This pain was increased by any attempts at movement, by jarring of the bed, and by any quick, irregular movement of the body.

The patient was operated on at Camp Grant, Feb. 10, 1919. Neurolysis of the median and ulnar nerves was performed at this time. After liberation, the nerves were surrounded by a fat transplant. The brachial artery had evidently been injured, for when the operation was performed, no pulsation could be detected in it distal to the wound. The median nerve was described in the operative findings as being bound down beneath the biceps muscle and kinked by scar tissue. The internal cutaneous nerve was not involved.

When examined, April 15, the patient held the forearm flexed at an angle of 80 degrees, with the hand raised and the fingers extended. The fingers were delicate and the whole hand appeared atrophied when compared to the other hand.

The skin was dry, there being no perspiration. A furfureaceous scaling was noted especially on the dorsal surface. The skin on the dorsum was white and shiny while that on the palmar surface was pink, there being no marked difference over the median and ulnar distribution.

All motions of the flexor and extensor muscles were limited. This limitation of motion was probably due to fear of paroxysms of pain which were induced by any attempt at movement. Extreme flexion of the fingers was limited by fibrosis.

The patient complained of a continuous pain over the hand which was more intense over the distribution of the median nerve and was aggravated by almost any movement. Exposure to air or to dry heat, especially a hot atmosphere, also induced a paroxysm, to prevent which the patient usually wore a glove soaked in cold water. When the glove was not worn the patient went frequently to the cold water tap and let the water run on the hand in order to secure relief. He assumed postures to protect the hand, which was usually held up, the body being inclined toward the left.

The patient's mentality and disposition became affected by this aggravating pain. He avoided other patients in the ward and often would be gone for long periods of time, evidently being desirous of being left alone. At times he would be found curled up in bed with the arm bent up and motionless and with the body curved toward the affected hand.

April 17, the ulnar and median nerves were exposed in the lower third of the arm. They were embedded in scar tissue from which they were freed. The median nerve was then injected with a 60 per cent. alcohol solution.

The patient experienced almost immediate relief from the pain. Motion returned; and although there was considerable atrophy, there has been a progressive improvement in the hand and a marked improvement in the health of the patient.

CASE 2.—Causalgia of the left foot. *Ulceration of the foot and leg resulting from maceration of the skin due to wrapping the leg with wet towels for weeks. Internal popliteal nerve surrounded by a small amount of scar tissue. Previous neurolysis without relief by fat transplant. Cure by alcohol injection of internal popliteal and long saphenous nerves.*

S. H. T. received a machine gun bullet wound of the left thigh at Château-Thierry, July 28, 1918. The bullet entered the anteromedial surface of the thigh about 8 inches above the level of the knee joint and made its exit at the same level on the external surface posteriorly. Ever since the wound had been received, pain had been noted along the back of the leg and inner side of the ankle and foot.

An operation performed at Camp Grant, Feb. 11, 1919, revealed scar tissue surrounding the sciatic nerve which did not, however, cause any gross pathologic change in the nerve. Neurolysis by fat transplant was performed. In the history it was noted that an ice bag was applied, February 24, to relieve this pain.

The patient was admitted to U. S. General Hospital No. 28, March 19. He said that he had had no relief from the pain as a result of the operation. It was aggravated by hot applications and irritation of any kind, but was relieved by cold.

This patient presented a pitiful picture. He remained in bed all the time. The foot and leg were wrapped in a towel which was kept soaked with water. This had to be renewed frequently, for cold water relieved the pain. As a result of this continued application of a wet towel, the skin had become badly macerated, and several large ulcers had formed on the foot, and multiple small ones on the leg from the opening and the breaking down of blebs. Movements were preserved but were limited, for any attempt at movement induced a paroxysm of pain.

April 24, the sciatic nerve was exposed above the site of the previous operation and the internal popliteal nerve was injected with 60 per cent. alcohol. This was followed by almost immediate relief of pain over the distribution of this nerve, but some pain still persisted.

It was noted in the history that prior to the injection all movements controlled by muscles supplied by the sciatic nerve were present. After the injection, flexion of the toes was lost and inversion and plantar flexion of the foot were weak.

After the injection there was loss of pain and tactile sense in the sole of the foot and back of the heel. There remained, however, marked hypersensitivity on the back and inner side of the leg down to the internal malleolus where sensory loss was complete.

Pressure on any part of the thigh, whether over the course of nerves or not, produced a sharp pain which started on the inner side of the knee and passed down along the inner side of the crest of the tibia to the internal malleolus, ending posterior to it. This pain had been present from the beginning and had persisted since the alcohol injection. Even the touch of the hand or a jar of the patient induced the same pain. A marked erythema was found along the entire length of the inner surface of the leg. The erythematous strip measured from 2 to 3 inches in width and extended down to the internal malleolus and back of it along the inner side of the foot. The pain did not seem to be influenced by the position of the foot.

June 23, the long saphenous nerve was exposed at the level of the knee joint and injected with 60 per cent. alcohol.

There was immediate relief from pain. It was noted in the history, June 30, that the ulcers were healing, that the erythema had disappeared, and that the patient was comfortable. Shortly after this, the patient was able to put on a shoe and walk with a cane, as the ulcers had healed.

By August 10, all motions had returned and the power of the gastrocnemius, soleus and tibialis posticus was practically normal. There has been no return of pain.

CASE 3.—Causalgia of left hand. *Chapping and ulceration of the skin due to dryness, causing a bleeding hand. Median nerve swollen and injected. Complete relief following injection of 60 per cent. alcohol.*

McM. H. R. received a perforating bullet wound of the left arm 1 inch above the elbow, unaccompanied by fracture, Oct. 2, 1918. Immediately after the wound was received, ulnar, median and musculospiral palsy was noted. Three days after the wound was received, the hand became painful. The pain was described as characterized by a burning sensation or by a feeling of being pricked by pins and needles. Within two weeks the pain became severe. The

Fig. 1.—Appearance of the hand and the position in which it is held in causalgia. The hand is atrophied and emaciated; more delicate and slender than the normal one. The skin has a glossy appearance and is dry, as the secretion of sweat is diminished or entirely suspended.

skin commenced to peel off the hand about the same time, starting first in the palm of the hand and on the palmar surface of the index and middle fingers. By December, 1918, there was a weeping erythematous eruption involving the entire hand with the exception of the dorsum of the thumb. It extended up to the wrist on the dorsal surface. The pain was aggravated by heat, but relieved by cold, especially by cold water. To relieve the pain, the patient wrapped the hand with a towel soaked in cold water.

For several months the condition was so severe that even the slightest jar of any portion of the body induced a paroxysm of pain. At times the patient walked on his toes to prevent jarring. Rubbing any part of the body, especially dry rubbing, caused a paroxysmal burning pain in the hand. Sudden noise would aggravate the pain. The hand always felt as if "hot and dry." The pain was not so intense in rainy weather. When the hand became hot and sweated profusely, the pain was intense.

By March, 1919, the musculospiral paralysis had practically disappeared, and the patient could extend his wrist. By May, the patient was able to close the hand almost completely. By July 1, he had recovered all the movements of the hand and wrist. The power of the muscles was practically normal.

The ulceration originally involved the entire palm of the hand and the dorsum as high as the wrist. The back of the hand gradually healed from above downward, and when first examined at U. S. General Hospital No. 28, there was only slight roughness, redness and scaling on the back of the hand. The palm was ulcerated and bleeding. The ulcers had a foul odor. Severe pain was experienced in the hand and forearm whenever pressure was brought to bear over the course of the median nerve at the level of the scar.

It was thought at one time that there might be a neuroma, but a satisfactory examination could not be made because of the pain induced by pressure over the course of the nerve.

September 6, the median nerve was exposed just above the old wound. The nerve at this point was reddened and injected. It appeared larger than the median nerve usually does but did not differ in consistency from a normal nerve. It was injected with 60 per cent. alcohol.

September 8, it was noted that the pain had been completely relieved; the hand was dry and healing.

September 11, there was no pain, the ulcers were healed, and the hand was dry and scaling.

Following the alcohol injection there was almost complete paralysis of the flexor sublimis digitorum, the flexor profundus of the index and middle fingers, and complete paralysis of the flexors of the thumb; also some weakness of the flexor carpi radialis and almost complete paralysis of the palmaris longus. Fair power remained in the opponens pollicis.

September 17, there was no pain. The hand, as described by the patient, felt "like a new hand." There had been con-

siderable return of motor power within the last six days, notably in the opponens pollicis and flexors of the middle finger. Power was beginning to return in the flexor profundus of the index finger. There was no return of flexion of the thumb at this time. The patient went home on a furlough.

COMMENT

The pain as a rule reaches its maximum intensity four, five or six months after the injury, then it gradually but slowly, sometimes very slowly, decreases in intensity. The fear of exciting paroxysms of pain may persist long after the pain has actually decreased in intensity, and patients will still resort to methods already described of controlling or preventing the recrudescence of the pain. Improvement in voluntary motion may not occur or may occur slowly even when the pain has subsided and the positions of the parts affected may still persist, resulting in the development of ankyloses which are corrected with difficulty and may render the hand or foot practically useless.

These three patients treated by an intraneural injection of 60 per cent. alcohol experienced almost immediate relief from pain. The ulcers and chapped, bleeding areas healed rapidly, and the paralysis resulting from the injection of the alcohol was temporary.

The early use of the muscles of the extremity affected prevented the development of contractures and atrophy.

In the first case in which the median nerve was injected, April 17, 1919, examination made September 25 revealed good power, which was practically normal in all the muscles supplied by the median nerve. In the second case, the internal popliteal nerve was injected, April 24, 1919, and, Aug. 10, 1919, an exam-

ination revealed that all the muscles supplied by this nerve had recovered motion and that the power of the gastrocnemius, soleus and tibialis posticus was practically normal. In the third case the injection was made, September 6; and September 17, motion was present in the opponens pollicis and in the flexors of the middle finger. Motion was beginning to return in the part of the flexor profundus attached to the index finger, but there was no return of power in the flexor longus pollicis.

Sixty per cent. alcohol seems in some cases to interrupt the conduction of sensory impulses, but not to interfere with the transmission of motor impulses. As

Fig. 2.—Complete recovery of motion in muscles supplied by median nerve after injection with 60 per cent. alcohol. This occurred within three months following the injection. Beginning return of motion was noted within three weeks.

is indicated by the excerpts from histories which have been given, motor palsies, when they do develop, are transitory and are rapidly recovered from.

When this injection is made, the nerves affected should be exposed under general anesthesia. The injec-

Fig. 3 (Case 2).—Swollen and macerated foot in a case of causalgia. For two months towels soaked in cold water were continually worn about the foot. These wet applications caused considerable maceration, associated with ulceration.

tion should be made above the wound or site of the injury, for in those cases in which the injection has been made below, the results have been temporary.

Fig. 4 (Case 3).—Scars on palm of hand and the palmar surfaces of the fingers indicate the extent of the ulceration. This foul smelling, ulcerated and bleeding area was healed five days after injection of the median nerve with 60 per cent. alcohol.

From 1 to 2 c.c. of 60 per cent. alcohol should be injected. As this is injected the nerve swells and becomes white, resembling in color a nerve that has been fixed in alcohol for histologic study.

Leriche has advocated in the treatment of these cases periarterial sympathectomy. This procedure of intraneural injection of 60 per cent. alcohol originally suggested by Sicard is so simple and the results are so satisfactory that it should be the operation of choice. Whenever neurolysis is performed in cases of causalgia it should be combined with an intraneural injection of 60 per cent. alcohol. Neurolysis, alone, does not control the pain in many cases, and in those in which there is some relief, it is but temporary.

OBSERVATIONS ON CHEST WOUNDS

REVIEW OF FIFTY-THREE CONSECUTIVE CASES*

HUGH CHAPLIN, M.D.

NEW YORK

The present article is based on a study of fifty-three consecutive thoracic wound cases admitted to the American Red Cross Military Hospital No. 2, Paris, France, from Aug. 20, 1918, to Jan. 31, 1919, a period of over five months. It includes all such cases admitted during this period. It is necessary to consider when comparing the results secured here that during the first part of this period this unit functioned as an evacuation hospital, whereas, later on, it became virtually a base hospital. Thus, early and late deaths appear in the mortality report. Thirty per cent. of the cases were received within four days from the time of wounding; 40 per cent. from four to fifteen days from wounding, while 30 per cent. were admitted later than fifteen days. Although a special effort was made to keep particularly complete reports, rushed conditions, especially during the first few months, often made these far from satisfactory. Particularly was this true of the records of many of the cases up to the time when the patients arrived here. Again, from the point of view of final results, length of necessary convalescence, etc., we are not in a position to make any definite statement, as our patients were in most instances transferred further to the rear as soon as they could be comfortably transported. The average stay in the hospital was forty-three days. In only eleven instances were we able to hear from them later, and then only by the briefest of letters, from one to three months after departure from this hospital, so that only a general impression could be safely secured as to their progress. Also a number of cases came to us when a nearby hospital was ordered to close. They were among its most serious cases, and in three instances death occurred within twenty-four hours, so that our observation of them was almost nil. Unfortunately, the ideal arrangement whereby patients go at once after wounding to a hospital, where they remain during their entire illness, is almost never found in times of great activity. No new methods of treatment were attempted by us, so that we have no innovations to offer. This study has been made, therefore, rather as a review of our experience with this class of cases, and also in the hope of corroborating facts previously noted in the many excellent articles already published by English, French and American surgeons. It may perhaps help to decide certain of the still debated

* From the American Red Cross Military Hospital No. 2, Paris, France.

* Owing to lack of space, this article is abbreviated in THE JOURNAL by the omission of several illustrations. The complete article appears in the author's reprints.

questions by the addition of further evidence for or against them. During this period also a number of isolated points of interest were noted and will be briefly dealt with.

STATISTICS OF CONDITIONS FOUND

Among the fifty-three cases considered in this article, 30 per cent. were perforating wounds; 60 per cent. penetrating wounds; 6 per cent. wide open wounds, and of the remaining 4 per cent. no record was made. Penetrating wounds were considered to be all those in which there was no wound of exit, even if the foreign body had emerged from the thorax and was lodged in adjacent structures. This attitude was taken because the foreign body might still remain in close proximity to the intrathoracic cavity and be directly connected with it by its tract, thus still acting as a possible focus of infection. In 53 per cent. of the cases, shell fragments were the offending instruments, machine gun bullets and rifle bullets in 40 per cent., and in the remaining 7 per cent. no record was made. Simple hemothorax occurred in 32 per cent. of the cases, of which 7 per cent. were large; namely, over 1,500 c.c., and 25 per cent. were less than this. Pneumothorax was reported present in a greater or less extent in 24 per cent., either with or without hemothorax or pyohemothorax. Roentgen examination has shown small pneumothoraces so often when they were not detectable by physical examination that it is quite likely that this figure is much too small. However, except in a very few instances, it is one of the least important intrathoracic conditions found in these cases. Pyothorax we found in 43 per cent. of all the cases. This figure, together with the 32 per cent. of simple hemothorax, would total 75 per cent., and leave 25 per cent. showing neither. However, as many of these patients came to us with insufficient

Fig. 1.—Insertion of a bronze wire rib-stay, apparently for the purpose of filling in the gap formed by the rib resection.

records of the conditions present soon after wounding, it is quite likely that some may have had sterile hemothoraces which had been drawn off or spontaneously absorbed before admission here. This would tend to increase the percentage of sterile hemothoraces, though still leaving some cases in which at no time was there any appreciable fluid in the injured thoracic

cavity. This was clearly shown by one accident case admitted about one hour after wounding and watched carefully for the following sixteen days.

CLINICAL COURSE OF VARIOUS GROUPS

In a general way it was possible to divide the cases into two main groups, from the point of view of their

Fig. 2.—The same case as Figure 1; condition of patient after removal of wire rib-stay; increased expansion of right lung and lessened pleural thickening.

clinical course: namely, those without and those with intrathoracic infection. The former could again be divided into two further groups: those cases without and those with hemothorax. The cases without hemothorax rarely showed any rise of temperature and frequently a normal pulse rate. There might be moderate cough and perhaps some spitting of blood for a few days or a week, if the patient had been received soon after wounding. On the whole, they were quite comfortable and normal and were kept in bed for a week or ten days merely because of their almost universal fatigue and as a precaution against the development of any complication.

In those cases with hemothoraces, on the other hand, a fever of from 99 to 101 was generally present, with a moderate rise in pulse rate, probably more cough of a nonproductive, nagging, irritative character, and increasing proportionately with the amount of fluid present. There was often dyspnea, even orthopnea in cases of large collection of fluid. But in none of these cases were the men as acutely ill, with the flushing of the face, feverish brightness of the eyes, the nervous excitability or the severe toxic dyspnea, such as so often accompanied many of the infected thoraces. Exploration revealed a bloody fluid, little changed, without odor and showing no bacteria when cultures were taken. Aspiration of a fair amount of fluid seemed to relieve the fever and the dyspnea and cough, so that frequently after one satisfactory aspiration, though the remnant of fluid persisted for many days, the temperature, and other undesirable symptoms, gradually became normal. Therefore, the mere presence of a moderate temperature with a hemothorax is no certain indication of its infection. But as one cannot be sure except by examination of the fluid, and as it must always be consid-

ered guilty until proved innocent, frequent explorations should be made and the cultures of the fluid taken to check up regularly its sterility while the abnormal temperature lasts.

Two groups could also be made of the infected cases received: those without thoracic drainage and the cases arriving after this had been secured. The former usually showed a steady and rapid rise of fever within two or three days and an equally rapid increase in the other signs of general toxicity. *Streptococcus hemolyticus* either in pure culture or mixed with pneumococcus, or *Bacillus aerogenes-capsulatus* was present in 70 per cent. of the infected cases. The general failure in strength was rapid, so that, without any treatment, a patient's condition might become serious in a few days. In the cases with drainage already secured, the toxicity might continue for three or four days and then gradually diminish with the fever. At times, however, the response to drainage would be immediate. It was not clear if this persistence of fever and toxic symptoms for a few days was due to an unsatisfactory drainage at first, that is, to the retention of infected clots of considerable size, or to a coincident pulmonary complication or merely to the fact that it required an appreciable time for the tissues sufficiently to throw off the toxins absorbed before drainage was provided. After the first week following thoracotomy, except for complications, the whole course was toward a steady return to the normal. Dyspnea and cough practically disappeared and the temperature remained around 90 to 100, touching normal generally in the morning. The pulse, however, was very likely to remain from 90 to 100 for a much longer period even with the patients quiet in bed. A discussion of the variations in the clinical picture due to complications will be taken up later under that heading.

TREATMENT

The consideration of the treatment of these patients falls under two headings: namely, those received immediately after wounding and those received later, the discussion of which will be limited to such treatment as was given in this hospital. Because of the paucity of records in many cases we could not draw many conclusions about the early treatment. It is still a much debated question whether it is best when the missile or bone fragments or pieces of clothing may be present and when there may be lung laceration and hemothorax, to open the chest widely at the earliest opportunity, remove all such foreign bodies, sew up lung and diaphragm tears, and close the cavity. There is, to be sure, a great difference between this procedure and merely a rapid débridement of the exit and entry wounds and suturing of any sucking opening, the operative shock in the latter being far less. It is not wholly clear from the scanty records at our disposal

whether the seventeen patients in this series operated on soon after wounding belonged entirely to the group of the more radical operation. Certainly the greater proportion did. Of these seventeen cases, eight, or 49 per cent., remained sterile, while nine, or 51 per cent., became infected later, requiring secondary thoracotomy for drainage. In each of these two groups there were three retained foreign bodies; and also in each the percentage of shell fragments and bullets as causative agents was approximately the same, so that these factors had no particular significance. Even when doing the work of an evacuation hospital, this organization was considerably farther to the rear than the average evacuation hospital unit, so that in almost every case the radical operations now under consideration were performed before admission here. Therefore, it was not possible to judge properly of their value, for the patients who might have succumbed to the shock of the operation would not reach us. Of those who did reach us, two out of the seventeen died, however, seven and thirteen days, respectively, after the original radical "clean-out and closure" operation.

One other word about the treatment in these cases before the patients were received by us. Three cases in which fractured ribs had been resected came to us from the same mobile hospital. Pleural infection had occurred requiring later thoracotomy. In each of these cases at the original operation a single bronze wire rib-stay had been inserted, apparently with the object of filling in the gap formed by the resection of part of the injured rib. This was passed through a hole drilled in at least one of the two ribs splinted. These were not cases of particularly large rib resection, and it was difficult to

Fig. 6.—Drainage wound closed; large pneumothorax; dense pleural adhesions at base.

see that any advantage had been secured. In none of these three cases was the wire attached to the second rib when the patients arrived here. In one of these cases, roentgen examinations revealed the free end extending into a large pneumothorax cavity. This was fortunately within reach through the thoracotomy opening, the loop was severed by a pair of stout scissors under the fluoroscope, and the fragments were removed by forceps. The other two cases were not so favorable, as the wires did not jut into pneumothorax cavities. As the drainage openings were closing satisfactorily, the wires were left in place for later removal under a local anesthetic when the existing process of infection had completely ceased. Whatever the original indication for these rib stays, they proved a troublesome complication in the later progress of the cases. Figures 1, 2 and 3 are roentgenograms of two of these cases.

The treatment in these cases after arrival at this hospital may be considered under two headings: non-operative and operative. The general procedure with all cases of chest wounds received was to have a

roentgen-ray examination of the chest made at once, even before sending the patient to the wards. In the case of the very sickest patients, one of whom was carried over in a semisitting position in his own bed from a nearby hospital, we had to defer the roentgen-ray examination until later. Whenever possible a stereoscopic pair of plates was taken, as these are by far the most valuable of the roentgen-ray examinations. When possible, fluoroscopic examination was also made, but when neither of these was possible, a single plate of the chest was taken with the patient on his back. One must, however, check up very closely by repeated physical examinations the roentgen-ray findings, and correlate them with the progress of the case. It is not usually practical to have many roentgen-ray examinations in every case, but the patients can be examined physically as often as desired. In general, it is possible to have one or two sets of plates made, and when the facilities are available, it is pure negligence not to use them freely. The ear or percussion finger will not tell the presence or location of a foreign body. Frequently also the skin and subcutaneous tissues are so changed either by hematoma from the blow, by a widespread cellulitis, or again from the presence of subcutaneous emphysema, that the exact conditions present within the chest cavity cannot be entirely determined by physical diagnostic means alone. If any fluid was found in a pleural cavity, an exploration and culture were made at once, unless it was a small amount and the temperature was normal. If sterile and of small quantity, it was not aspirated but examined at four and five day intervals so long as the elevated temperature or any other symptoms of infection continued. In all cases of hemothorax of approximately more than 100 or 200 c.c., it was the practice to aspirate as nearly dry as was possible in the belief that convalescence would be shortened. In all except two cases, aspiration was deferred to six or more days after wounding.

Aspiration was performed on eighteen patients altogether: eight once, nine twice, and one four times. Never were more than 1,200 c.c. removed at one time, and no cases of infection of the hemothorax occurred as the result of aspiration. The patients were kept in a sitting or semisitting position during the procedure. A careful anesthesia of the skin and parietal pleura with procain was first secured. This is quickly and simply secured, and makes the aspiration painless. When aspiration may have to be repeated frequently, in case the patients are extremely weak and ill, as they often are, every little refinement of technic, especially when so simple, should be used. When repeated aspiration was necessary, its frequency was determined by the amount of fluid present and the symptoms caused by it, such as dyspnea, cardiac excitability, general restlessness, cough and also the persistence of a moderate elevation of temperature. In large collections it was done every day or two until the quantity of the fluid had been markedly reduced;

or in moderate sized collections, a second and final aspiration might be layed for a week, as the remaining fluid was often absorbed quickly of itself.

The condition of the blood in the pleura has often varied considerably. It might be fairly thick and uniform, or thin and mixed with clots. Not infrequently the needle had to pass through repeated and firmly fixed partitions of clotted blood in order to reach the intervening layers of the thin fluid blood. If one is not certain of the amount of fluid in the chest, he is apt to stop after emptying a single small pocket and miss the main collection of fluid, for fear of doing damage to the lung by persistent attempts to penetrate to various depths and in various directions the tough wall which he takes to be the visceral pleura. If the patient can be in a semiupright position, held firmly by an attendant so that he can relax; if also one has not unnecessarily excited him to rapid respiration by undue pain; if the needle is sharp, of fairly large bore and rather short point, and if one avoids the obviously dangerous regions, it would seem quite safe to explore thoroughly even if the lung were to be punctured in the process. We have seen no undesirable complications from it and believe that one must persist in the

effort actually to remove the fluid when one is sure it is there. Some chests, however, would appear to contain merely a mass of blood clot. There was one such case in this series in which, after several thorough attempts to remove what appeared, on examination, to be a moderately large fluid collection, it was necessary to leave it alone. We have not used the method of replacing the fluid aspirated, in the case of large collections, with oxygen. That would seem to be advisable if it permits the cavity to be more completely drained at a single time; for, though aspiration is simple and not dangerous, the fewer of such procedures needed, the bet-

Fig. 9.—Drainage wound closed; small pneumothorax at left base; good lung expansion; same case as Figure 7; seventy days after thoracotomy.

ter, particularly in men severely wounded, who are as a rule also thoroughly fatigued.

The nonoperative treatment of infected hemothoraces, and pure empyemas, without hemorrhage, is simple, though considerable judgment is needed to know when and how long to depend on it. In brief, our practice has been to employ repeated aspiration at from one to two day intervals in all cases in which it appeared that patient was too ill for the moment to stand a satisfactory operation for drainage, and when immediate relief was needed. Frequently a rapid, painless aspiration of as much fluid as could be readily obtained, together with a dose of morphin, would give the one or two days of comparative comfort necessary to raise the patient's resistance sufficiently to allow the operation to be done with relatively small danger. In certain cases in which the toxemia did not depend on the quantity of fluid present, or when aspiration, for one reason or another, was not complete enough, free operative drainage in spite of the operative risk seemed best. One cannot rely on nonoperative preliminary aspiration in every case, but must be guided by the particular conditions found in

each case. How long to persist in aspiration if temporary relief is given depends largely on whether the patient's condition can be kept good until the fluid becomes a thick pus and the empyema localizes. There are frequently larger or smaller blood clots which cannot be aspirated and which should be removed as soon as possible, so that when these are present an earlier recourse to operative drainage is wise. Then, lastly, there are some cases in which the patient's excellent condition takes from operative procedure almost all its dread. In these there is no particular reason for delaying it. In brief, then, aspiration in these cases is merely to be used as a bridge of the dangerous gap between the time when some relief is essential but the general condition is too critical for operative procedure, and the time when the patient's resistance has improved enough to stand these more satisfactory measures of relief.

Two types of operation are employed at this stage: The first consists of a wide opening secured by using

Fig. 12.—Perforating shell wound of right apex; compound, comminuted fracture of right scapula; suppurating tract; no pleural infection.

a strong screw rib-spreader. This permits a thorough exploration of the pleural cavity and search for foreign bodies, as well as the removal of infected blood clots. It is not a minor operation and entails considerable shock; but, if there is reason to believe that blood clots are present and the man's condition will permit of it, these should be removed. The same thing applies to all other foreign bodies if they can be reached without unduly increasing the trauma or length of the operation. It would seem to insure a freer drainage and a more certain, shorter and more steadily progressive after-course than the second type of operation; namely, the ordinary thoracotomy with merely the insertion of a double rubber drainage tube. The latter operation has the great advantage of being particularly suitable for the use of local anesthesia and the consequent diminution of shock. When careful anesthesia is produced, it is a comparatively simple operation; but it does not permit of search for the foreign body or cleansing of the cavity of clots. It should be reserved, therefore, either for cases with

thin, homogeneous, clot-free fluid or for those cases in which the shock of the more radical operation could not be tolerated.

When shell fragments are present in the lung and there is no infection, they should not be removed except in the rare instance when they seem to be the cause of severe pulmonary hemorrhage. In the presence of infection of the pleura, our limited experience has led us to feel that, although a definite attempt at removal of the foreign body should be made, it should be left in place if not extractable with fair ease, because of the trauma incident to opening up fresh lung tissue. Eleven drainage cases were observed until the operative wound was closed. In three of these in which the shell fragment was present, the average time to closure was forty-two days. In the remaining eight cases without foreign body, the average time to closure was forty-eight days. From these figures it would appear that the presence of missiles in the lung has no retarding effect on the wound closure. Nor is it clear that their presence favors the occurrence of complications such as are dealt with later. Out of our thirty-two penetrating chest wounds, twelve, or 38 per cent., experienced some complication referable to the wounding; whereas of the sixteen perforating wounds only five, or 31 per cent., were complicated. However, of the twelve patients with foreign bodies in the lung when discharged from this hospital, only 33 per cent. were complicated; whereas complications occurred in 39 per cent. of the cases in which the missile was removed. In all these deductions it is necessary to bear in mind that they are based on a very small series. Yet, with this reservation, it is quite possible that they may point the way, in certain disputed questions, to the wiser course to follow. In this instance it would appear that the practice of insisting, in almost every case of infected intrathoracic penetrating wound, that the foreign body be removed at all costs is not wise, and that only in case it can be found with comparative ease and without obvious danger to the patient's condition should search be continued.

PERIOD OF RECOVERY

The period of recovery presents interesting points for consideration. Blow bottles were given to the patients just as soon as they were strong enough to use them. It is my impression that they were of benefit; and although started often at once after operation in the infected cases, we saw no bad effects that might have been laid to too early employment.

In most of the cases the drainage tubes were continued in place, though steadily cut down in length and diameter almost to the time when the wounds were ready to close permanently. In the few isolated cases in which the tubes were removed early, it was necessary to replace them very shortly to reestablish the drainage and reduce the coincident temperature. Careful daily dressings until the temperature is practically normal, the freedom of drainage assured, and its amount largely diminished, are essential. This has included replacing the tube each time by a fresh one. Whether or not to irrigate the cavity, and if so, with what solution, are questions which have received much general attention recently, both in empyema following chest wounds and in the postpneumonic type. In a few cases a gentle irrigation with salt or with surgical solution of chlorinated soda (Dakin's solution) was employed by us each day when the wound was dressed.

Patients were selected with the empyemic cavities circumscribed and apparently well walled off. Three of these patients, however, developed broncho-empyemic fistulas and only by very good fortune escaped serious consequences from the passage of the irrigating fluid

Fig. 14.—Shell fragment in middle of left lung; surrounding consolidation and probable abscess.

into the lung through the fistula. All three patients in whom this complication was noticed remarked that they tasted the solution. Two were thrown into violent fits of coughing and were nearly suffocated for the moment, while the third, though not troubled so much at first, developed a small bronchopneumonia around the fistula as the result of the fluid's irritating presence in the lung at that point. Therefore, although we made no systematic use of empyemic-cavity irrigation, our small experience was unfortunate and suggested that the occurrence of broncho-empyemic fistulas was not infrequent and that they might even be caused by the irrigations.

During the week or ten days immediately following operation for drainage, it was often very difficult to determine with certainty the cause of a persistent elevation of temperature and symptoms of absorption. These symptoms may have been due to retained blood clots blocking good drainage, or to a smaller or larger patch of bronchopneumonic consolidation. With us, it was necessary to consider always the intercurrent of an attack of influenza, as the period covered by this paper was that of the great, world-wide influenza epidemic. Frequent physical examinations, leukocyte and differential blood counts, and especially stereoscopic roentgen-ray plates and fluoroscopic examinations were absolutely necessary to give one a constant and clear picture of exactly the conditions present.

Figures 4 and 5, roentgenograms taken during such periods of uncertainty, show how difficult it is, even with the aid of repeated roentgen-ray examinations, to interpret the symptoms properly. The first case (Fig. 4) is that of a perforating wound of the right upper lobe, complicated by a moderately large hemothorax which clotted badly and became infected. Thoracotomy was done under local anesthesia and the clots were not thoroughly removed. It seemed quite certain

that they prolonged the discharge for weeks until entirely digested. During this time it was a constant question whether or not there was some hidden sacculated pocket of pus not draining. The lower portion of the cavity anteriorly, where there was considerable dulness and a roentgen-ray shadow, was frequently needled for fluid but without result. There was also a definite, persistent and clearly outlined shadow in the upper and outer portion of the affected side suggestive of a localized empyema at that point. Being high up in the axilla, it was very difficult to reach even with the exploratory needle, so that exploration was delayed for a number of days. It so happened that about this time the drainage became freer from the thoracotomy wound, the temperature dropped, and the patient began an uneventful recovery. The shadow persisted, however, so we were constrained to believe it was not due to anything other than thickened pleura and that elevation of temperature was caused by the slowly digesting blood clots. The second case (Fig. 5) shown in this connection was somewhat similar, being that of a penetrating wound with a shell fragment lodged in the left upper lobe. No pneumonia, pneumothorax or hemothorax was present, and yet there was a high fever and toxemia for from three to four days after admission. The patient had the same dense shadow in the upper outer region of the left thorax, which was suspected of being a localized empyema. He did have, however, a moderate subpectoral abscess at the wound of entrance. This was drained freely by incision, with a complete subsidence of symptoms, though the roentgen-ray shadow persisted a long time. This is a good example of a case in which no one means of diagnosis could be relied on. The frequent careful use of all should, however, clear up most obscure cases.

Fig. 15.—Large perforating left lung tract surrounded by fibrous tissue; consolidation resolved; good lung expansion. Same as Figure 14 but with foreign body removed.

Eleven of the cases in this series with empyemic drainage wounds were observed up to closure. The shortest time required was thirty-three days in one case, the longest sixty days in one, while the average number of days was forty-seven. As stated before,

those with the missile still in the chest averaged forty-two days, while those free of any foreign body took forty-eight days. It has seemed that the persistence of large clots, not cleaned out at operation, has prolonged the closure.

It was interesting and instructive to watch the change taking place in the chest as the discharge lessened and the time for closure approached. Frequently after the discharge had become scant and thin and the temperature remained normal, the wound would close while a large pneumothorax still persisted. This is well shown by Figure 6. Now and then, however, the pneumothorax contracted gradually down and had practically disappeared when the drainage wound closed.

The final intrathoracic functional disability observed both in the noninfected and the infected cases was surprisingly slight. In sixteen cases of noninfected hemothorax, practically all of which were aspirated nearly dry, 56 per cent. had good lung expansion, 38 per cent. fair expansion, and only one case, or 6 per cent., poor expansion on discharge. In the last case the patient had to be evacuated with a large hemothorax still present. He was heard from two months after leaving our observation, and though he had not been aspirated again, he reported that his lungs gave him no trouble at all and that he felt in excellent health. Of sixteen empyema drainage cases, in eleven of which closure had taken place before the patients were transferred from this hospital, 44 per cent. showed good lung expansion, 44 per cent. fair and 12 per cent. poor expansion. It was particularly interesting to see how quickly the expansion would increase in cases of long standing intrathoracic suppuration with considerable fibrosis. Figures 7, 8 and 9 show this point particularly well.

COMPLICATIONS

Complications directly traceable to the chest wound were present in twenty-four cases, or 45 per cent. They were: bronchopneumonia and lobar pneumonia, purulent pericarditis, general septicemia, secondary hemorrhage, influenza, broncho-empyemic fistula, fibrinous and serous pleurisy, toxic diarrhea and pulmonary tuberculosis. Of these, bronchopneumonia was the most frequent, occurring in eight, or 33 per cent., of all cases. In all except three of this group it was in the opposite lung from the injured side. This does not include the moderate infiltration generally present in the lung tissue immediately about the track of the missile. In one of these cases it appeared that the pneumonia was just enough to cause death in an otherwise thoroughly exhausted patient. In three others which were not fatal it was a serious com-

plication. General hemolytic streptococcus septicemia occurred once, causing death. Purulent pericarditis was present once, causing death. It was hard to detect this condition because a complete unilateral pneumothorax with what appeared to be a resulting displacement of the heart to the opposite side obscured what was really a distended pericardial sac. The partially collapsed lung on the pneumothorax side was another source of error appearing to account for the altered cardiac roentgen-ray shadow on that side. In this case, unfortunately, no audible signs of pericarditis were detected at any time. Figure 10 shows the conditions in this case. There was one case of intrathoracic secondary hemorrhage from intercostal vessels, causing death. The two cases of broncho-empyema fistula have already been mentioned. One of these patients left us with his drainage wound healed, and the patient gaining daily in strength. The other patient's wound was still open. The drainage in this case was not as favorable, so that it will

undoubtedly take longer to heal. In the one case of diarrhea included here, no organism could be found in the stool. The condition persisted until drainage of an infected hemothorax was provided, after which it cleared up promptly. The infecting agent in the thorax was the bacillus of influenza. It was a late infection of a previously sterile hemothorax, very probably of the same origin as the severe accompanying bronchitis, although unfortunately the predominating organism in the bronchial secretions was not determined. The diarrhea appeared to be definitely of toxic origin.

In connection with this case of influenza infection of a hemothorax, there

was one other case which developed quite late a bronchopneumonia in the left lower lobe, which had been the seat of a penetrating wound. Influenza bacilli in pure culture were recovered from the sputum. A moderate serous effusion occurred in the left pleura but continued sterile, and after one moderately large aspiration it was absorbed without further trouble.

Moderate and severe attacks of influenza occurred in six cases. They were without serious consequence, but were of interest as the aching, which in a non-wounded man is especially noticeable in the arms and legs and back, were in each of these cases especially referred to the region of the wound. It was often difficult at first to differentiate an attack of influenza from a pocketing of pus within the injured chest cavity. In influenza complications, however, the negative findings by roentgen ray and the usual low leukocyte count of influenza were of great differential assistance.

In only one of our cases was pulmonary tuberculosis found. This was in a young man (without pre-

Fig. 16.—Penetrating shell wound of left axilla; abscess in left upper lobe, draining through wound; no pleural infection.

vious tuberculosis history) who sustained a perforating wound of the left upper chest shattering the clavicle and scapula. The pleural cavity became infected and required thoracotomy and drainage. The patient was admitted to us ninety-six days after wounding. At that time he showed at the opposite apex a very generally scattered tubercular infiltration. The bacilli of Koch were present in the sputum. He was emaciated and presented a sharply remittent fever which reached each day between 103 and 104. It was suggested that this had probably been a hematogenous infection from some previously moderately quiescent focus in the wounded lung. It is one of the very few similar cases observed among the wounded of the American Expeditionary Forces. The roentgen-ray findings in this case are shown in Figure 11.

MORTALITY

In considering the mortality, reference should be made again to the fact that during the period covered by this paper this unit acted for a time as an evacuation hospital, and also that more than one third of the deaths occurred within twenty-four hours after admission from a nearby hospital compelled to close and transfer all its cases. If we consider these facts, the otherwise high mortality of 15 per cent. is better understood. Of the eight deaths, the average day of death in four cases was the thirty-third day after wounding; in two other cases the average day of death was ten days after wounding, and for the remaining two the figures were not available. Three patients died within twenty-four hours after admission, one four days after, and one each on the ninth, tenth, fifteenth and sixteenth day.

Eleven per cent. of our patients wounded by shell fragments died, while only 5 per cent. of the patients wounded by bullets died. All of the eight deaths occurred in infected cases. The causes of death were as follows: bronchopneumonia occurred twice, shock twice, while lobar pneumonia, purulent pericarditis, postoperative intercostal hemorrhage and *Streptococcus hemolyticus* septicemia each occurred once. Our statistics did not show any direct connection between the type of organism present and the percentage of mortality. Seventy-five per cent. of the cases resulting fatally were complicated. Of the cases in which recovery took place, only 33.3 per cent. showed such complications. The complication in the fatal cases seemed to be the direct cause of death. The two important deductions are, therefore, a reiteration of already well-known facts, that shell wounds are far more serious than bullet wounds, and that complications are much to be feared because of their high mortality.

Apart from the groups of cases already considered, there were a few special conditions of considerable interest. One was a perforating wound of the right upper chest near the shoulder, comminuting the

scapula badly. Figures 12 and 13 show the outward appearance of the wounds and the intrathoracic condition. For a number of weeks there was a continuous tract through the chest. This gradually cleared, fibrosed, contracted to a cord, the surrounding traumatic consolidation resolved, and the wound closed satisfactorily. The other two were penetrating wounds. In one case (Figs. 14 and 15) with a posterior wound of entrance, two pieces of shell were found close together toward the anterior surface of the left lung just above and inside of cardiac apex. They were removed by anterior incision, a complete perforating tract being formed. The pleura remained uninfected and the same course was followed to closure as in the first case. The second penetrating wound case showed a piece of shell 1.5 by 0.5 by 4 cm. in size which had entered high in the left axilla and penetrated deeply into the upper lobe of the left lung, forming a lung abscess but sparing the pleural cavity. Figures 16, 17 and 18 should be seen in this connection. The fragment was removed and drainage improved. The abscess had contracted greatly when the patient was transferred.

One more freak case showed a great deal of the lower sternum and the sternal attachments of the right and left lower ribs shot away in such a manner as to produce a gutter wound. The mediastinal space was open for an area of 4 by 8 cm., showing clearly the outer surface of the parietal pericardium. The heart beat was clearly visible. Each pleural cavity contained between 50 and 100 c.c. of thin, slightly bloody, sterile fluid; but only a moderate superficial infection of the wound occurred which quickly cleared, the pleura and pericardium escaping entirely.

In this series there were only two cases in which

Bacillus aerogenes-capsulatus was present in pure culture in the hemothorax. One of these men was wounded twenty-seven days before operative drainage was finally provided. When admitted, he was in great distress and pain from intrathoracic pressure. An aspiration of 500 c.c. of bloody purulent fluid gave no relief. Unfortunately, the needle was still below the upper level of fluid and so did not afford direct relief of air tension. After the aspiration there did not seem to be a great quantity of fluid left, but the intercostal spaces continued to bulge. It was only when free drainage by thoracotomy was provided that relief came. From observations in this case we were inclined to believe that the gas bacillus had been the positive agent in producing the increased intrathoracic tension. The second case of pure culture, although it was over two weeks after wounding before thoracotomy was done, showed no undue intrathoracic tension. Nor was this present in four other cases in which this organism was mixed with the hemolytic and nonhemolytic streptococcus.

The symptoms experienced immediately after wounding agreed entirely with those so often and so

Fig. 17.—Large shell fragment in abscess of left upper lobe; consolidation above; lower lobe normal. Same case as Figure 16.

well reported elsewhere. Generally there was the sensation of a heavy blow followed by dyspnea, cough and frequently hemoptysis, which was generally moderate and lasted only a few days. Now and then it was severe or continued for a week or two. We have no information as to how often the hemorrhage was

Fig. 18.—Apical consolidation resolved; foreign body removed; fibrosis about cavity; good lung expansion. Same case as Figure 16.

fatal. There was occasionally profound weakness and fainting or temporary weakness from which recovery was rapid. Very frequently in clean perforating bullet wounds the lack of symptoms was extraordinary. Men reported having walked alone or with assistance as much as five miles before collapsing.

CONCLUSION

The following facts seem fairly clear: The diagnostic means of needle puncture and stereoscopic and fluoro-

SUMMARY OF FIFTY-THREE CASES OF INTRATHORACIC WOUNDS

	No. of Cases	Percentage
Mortality	8	15

* Of penetrating wounds.

scopic roentgen-ray examination should be freely employed. As a nonoperative measure, repeated aspiration has a very important place in the treatment if judgment is used in employing it. In cases requiring merely thoracotomy and drainage or when this is all that can be attempted, local anesthesia with 1 or 2 per cent. procain is of great value. On the contrary, when large infected clots are present and the man's condition will permit it, a more radical operation is to be preferred. Foreign bodies in the lung are tolerated with unusual ease both in noninfected and in infected cases, so that, whereas, in the latter cases, an attempt should

be made to remove them, no great dread need be entertained, so far as our early information goes, if they must be allowed to remain. It is most encouraging to see how much lung expansion can occur even after the severest injuries and infections within the pleural cavity.

We cannot yet say with certainty what is the best type of early operative treatment for these cases. This question (and many others still obscure) is bound up inextricably with the as yet unsolved administrative difficulty of providing special hospitals for thoracic wound cases near enough to the front that a sufficient number of patients can be sent there directly after being wounded and kept there under continuous observation during their entire convalescence.

FALSE PNEUMOTHORAX *

B. P. STIVELMAN, M.D.

Medical Superintendent, Montefiore Home Country Sanatorium
BEDFORD HILLS, N. Y.

Few localized pneumothoraces can be diagnosed without the aid of the roentgen rays. Indeed, most recent observations on interlobar pneumothorax¹ and pleural and pulmonary annular shadows² are based solely on the routine roentgenologic study of patients suffering from pulmonary diseases.

There are rare cases, however, in which a rapid roentgenologic examination may suggest a localized pneumothorax or hydropneumothorax, when in reality neither condition exists. French writers, who were among the first to recognize this condition, applied the term "faux pneumothorax" to these supposed roentgenologic aberrations. These false pneumothoraces do

Fig. 1.—Apparent hydropneumothorax at left lower lobe, showing advanced fibroid changes throughout the left lung suggesting evidence of multiple cavitation, with the heart drawn markedly to the left and upward.

not cause any definite subjective symptoms, and the physical findings over the area involved are those of

thickened pleura with retraction of the lung tissue. There is usually a fluid level in the region of one or the other of the lower lobes of the lung, where these pneumothoraces usually occur. Their appearance either fluoroscopically or on flat or stereoscopic plates is characteristic of localized hydropneumothorax.

Fig. 2.—Same patient six months later, showing the fluid level of the apparent hydropneumothorax one inch higher after the ingestion of 16 ounces of water.

Careful observation, however, will disclose the fact that such air collections are extrathoracic and are situated below the diaphragm, which is either pushed or drawn high up into the hemithorax. When situated at the right lower lobe, such gas collections are frequently due to a subdiaphragmatic abscess. The gas formed pushes the diaphragm high up into the thoracic cavity, thus causing the adjacent lung tissue to collapse. When situated at the left lower lobe, they very frequently are due to extreme pulmonary fibrosis with marked upward traction of the diaphragm, and to a more or less dilated stomach. In the former instance the fluid level is caused by the gas-containing abscess, and in the latter instance by the stomach contents.

The paucity of reports of this condition in the literature prompts the recording of all such cases, for by so doing a great deal of inconvenience and some danger may be avoided when considering exploratory puncture. Lebon relates one such instance from his service at the military hospital at Buffon. A soldier's stomach, which was punctured for diagnostic purposes, was found drawn high up into the thorax, thus simulating an intrapleural fluid and air-containing space. It is reasonable to assume, however, that such instances occur more often than the number of reports on the subject would indicate.

I observed a case of pulmonary tuberculosis in which the lesion at the left lower lobe had been interpreted, at a hospital for the tuberculous, as a thickened pleura with retraction of the diaphragm. After a physical and roentgenologic examination of the patient, on her admission to our sanatorium, a diagnosis of pulmonary tuberculosis, complicated by spontaneous localized hydropneumothorax, was made (Fig. 1). Many months of observation and ultimately a more careful roentgenologic examination proved that the supposed hydropneumothorax was a markedly retracted stomach.

REPORT OF CASE

S. K., aged 27, admitted to our institution in February, 1919, gave a typical history of pulmonary tuberculosis, with recurrent attacks of chills, fever, sweats and hemoptyses, extending over the previous five years. Physical exploration of the chest disclosed evidence of consolidation and marked cavity formation of the upper half of the left lung with a very dull note on percussion and feeble breathing over the left base. Neither splash nor coin sign could be elicited. The condition at the left base was thought to be the result of a thickened pleura. The right upper lobe showed evidence of moderate tuberculous infiltration. The heart was drawn upward, markedly to the left. Fluoroscopic examination of the chest confirmed the physical findings in general, but instead of the thickened pleura at the left base we were astonished to find a marked hydropneumothorax. A roentgenogram (Fig. 1) taken the same day confirmed the fluoroscopic findings. The patient's general condition improved during the following six months, and repeated physical examinations during this period disclosed no evidence of the existence of the hydropneumothorax, although the roentgenogram disclosed the same condition as seen in the first examination.

Contrary to expectation, the air in the supposed pneumothorax was not absorbed to any appreciable degree. Furthermore, the fluid level varied with the ingestion of food, being higher after a full meal (Fig. 2), lower before breakfast, and entirely absent on fasting (Fig. 3). This prompted us to give the patient a barium meal which, on fluoroscopic observation, was seen to reach the supposed hydropneumothorax and cause a splash and distortion of the fluid level. Capsules filled with barium were seen to enter this air pouch and rest on the fluid level before disintegration (Fig. 4).

COMMENT

When these false pneumothoraces occur on the left side they must be differentiated from transdiaphragmatic hernias, which, with the exception of the few congenital cases reported in the literature, are almost invariably due to extensive shrapnel, gunshot and stab wounds, and give rise to acute symptoms, as dyspnea,

Fig. 3.—Same patient after fast of fourteen hours, showing absence of fluid level in the air-containing space at left lower lobe.

hemoptysis, hematemesis, fever and chills, which are referable to both the left lung and the stomach. Before the roentgen ray was extensively employed, a diagnosis was made in many such cases following a history of injury, tympanitic note over the area involved, or most often as a result of the protrusion of some of the abdominal contents through the wound in the chest

wall.³ A transdiaphragmatic hernia may be recognized roentgenographically by the appearance of part of the stomach above the diaphragm and part below.

Patel and Jaboulay,⁴ however, assert that a number of diaphragmatic hernias present no clinical histories, but are discovered at necropsy. It is reasonable to assume that these observers referred to the congenital form of this condition, for recent reports would indicate that all traumatic diaphragmatic hernias give rise to unmistakable symptoms which are usually corroborated by careful roentgenologic examinations.⁵

Extrapleural pneumothorax at the site of the needle puncture has been described by Gwerder,⁶ who reports a case of pneumothorax in which a large gas pouch was formed extending from over the fifth to the eighth rib in the left anterior axillary line, presumably the result of high intrapleural pressure. The pouch, which distended on coughing and sneezing, could be reduced by firm bandaging.

Barjon and Courmont mention a case in which it was doubtful whether the diagnosis should have been

3. By means of the fluoroscope a barium bolus may be seen to enter the supposed hydropneumothorax, causing a splash and distorting its fluid level.

4. A localized hydropneumothorax may be simulated by the diaphragm and stomach, when they are in a high position due either to extreme pulmonary fibrosis or gastrectasis. This possibility should be considered when an exploratory puncture is contemplated.

RADICAL ABDOMINAL HYSTERECTOMY FOR CANCER OF THE CERVIX UTERI

A REPORT OF END-RESULTS, SHOWING AN
UNUSUALLY LARGE PERCENTAGE OF
FIVE-YEAR CURES *

FARRAR COBB, M.D.

BOSTON

This report of end-results in the radical abdominal hysterectomy for cancer of the cervix uteri is made with much satisfaction. It deals with a series of sixty cases, not a very large number as compared with that of some operators, but large enough to prove that cancer of the cervix may be cured in a large percentage of cases by the properly performed radical operation. I have had 57 per cent. of five-year cures in my personal work as shown here, and an operative mortality of 11.6 per cent.

RADICAL HYSTERECTOMY AS A CURATIVE MEASURE

I fear that the report of such a large percentage of five-year cures may be received with skepticism by some, especially by those who have doubted the curability of this disease; and I am compelled to state that in following up my patients, the number of those alive and well for many years after operation has surprised as well as pleased me.

All the cases were undoubted cancer of the cervix clinically, and in all cases but one there was a corroborative microscopic diagnosis made by a pathologist of established reputation, in almost all instances by one of the pathologic staff of the Massachusetts General Hospital. It has been possible to follow up every case, and each patient has been examined by myself periodically.

The cases were by no means all selected favorable ones, and there were only two cases of very early microscopic diagnosis. On the other hand, the majority were hospital cases of varying extent, many of them more than moderately advanced cases of cancer, and a few were borderline cases in which the hope of cure by operation seemed very small (Cases 1, 6, 9, 21, 24 and 30).

I want to emphasize by means of this paper the fact that the radical abdominal operation will cure cancer of the cervix in a large number of cases, and that in skilled hands it should cause no excessive operative mortality.

For many years I have been working, writing, lecturing on cancer of the uterus: its early diagnosis, the need of pathologic examinations, and the value of radical hysterectomy as a curative measure. It is borne

Fig. 4.—Same patient, showing height of fluid level after drinking about 24 ounces of fluid, with a barium capsule projecting from the fluid level about five minutes after it was taken.

pyopneumothorax or retracted stomach. Lebon⁷ describes two cases of false pneumothorax, and more recently Aimé and Solomon have reported a case in a tuberculous patient.

The diagnosis in such conditions should present no great difficulty when it is borne in mind that:

1. These extrapleural air pouches are characterized by their failure to absorb the gas they contain. A true pneumothorax tends invariably to spontaneous absorption.

2. The height of the fluid level in a false hydro-pneumothorax varies most decidedly with the ingestion of food and with the emptying of the stomach. The fluid disappears on fasting.

in on me, however, that many medical men and even many surgeons still doubt its curability by operation, and that many patients seen sufficiently early to have a good chance of cure by hysterectomy are treated by radium or by the ill-advised Percy cautery method. It is absolutely certain that radium and the cautery cannot cure cancer of the cervix, no matter how valuable they may be as palliative treatments in the inoperable cases. The danger of the widespread exploitation of radium and the Percy method of cautery treatment is the depriving of certain persons of a chance of life by the only curative procedure, namely, hysterectomy.

My personal work on the whole question of cancer of the uterus in its different forms, its cure and its palliation, covers a period of twenty years. I performed my first hysterectomy in 1901, and it is interesting to note that this patient, my first case, operated on in my younger and more inexperienced years, is one of the cured cases today, being alive and in perfect health eighteen years afterward (Case 1). For several years, as one of the surgeons at the Massachusetts General Hospital, I held the special assignment of cancer of the uterus, seeing and operating on all the patients that came into the wards, both those with cancer of the body of the uterus and those with cancer of the cervix. In 1912 and again in 1914 and 1915, I published papers reviewing my work at the hospital and analyzing a series of 420 cases admitted to the hospital in the fifteen years from 1900 to 1914, including ninety-eight cases of my own. These papers deal with the general questions of operability, diagnosis, choice of operation, palliative treatment, etc.¹

In this paper, I wish to consider only my personal work in radical hysterectomy and the end-results thereof, including a summary of each cured case, touching briefly on the technic of the operation and the lessons that experience has taught me.

I have performed personally sixty radical abdominal hysterectomies, what generally are called Wertheim operations, but differing from Wertheim's method in certain essential modifications of my own which, while making the operation none the less radical, make it somewhat safer. Thirty-one of these operations were performed at the Massachusetts General Hospital and twenty-nine in my private practice. Thirty-five were performed more than five years ago, previous to 1915, and of these, twenty-six were hospital cases. My percentage of five-year cures has been 57.1. An analysis of my end-results in detail will be given at the end of this paper.

Among the sixty cases, there were seven operative deaths, a mortality of 11.6 per cent. One death from intestinal obstruction occurred two months after the operation and, therefore, might be omitted; but owing to the fact that the patient had not left the hospital, I have included this case in my immediate mortality, as also one other patient who died in the sixth week of septic iliac thrombosis. Five deaths occurred among my first thirty cases; but in my last thirty cases, only two: a reduction in mortality commensurate with steady improvement in technic. Three patients died from shock, largely caused by hemorrhage. The control of hemorrhage, especially toward the end of the

operation, is one of the most important technical questions. Two patients died of general peritonitis.

The operation comprised the removal of the uterus and a liberal portion of the vagina, with as much of the parametrium as possible, through a median abdominal incision, with ligation of both internal iliac arteries and removal of the regional glands when enlarged and palpable. It is a difficult operation and should be performed only by trained surgeons; but in such hands, it should not involve an excessive mortality, certainly not over 15 per cent. In my whole series of sixty cases, it was 11.6 per cent., and in my last thirty cases, only 6.6 per cent. Wertheim's mortality, in his last series of cases, was 12 per cent.

The operation should not be performed in the presence of marked obesity or debility. A renal function of 25 per cent. or less would contraindicate the method.

Fig. 1 (Case 16).—Anterior view of specimen, showing wide removal of parametrium.

With very fat or feeble patients, the more rapid and safer, but far less curative, simple vaginal hysterectomy should be the method of choice. The radical vaginal hysterectomy of Schauta and Schuchardt I have found more dangerous and difficult than the abdominal method, and the postoperative sequelae distressing.

CASES FAVORABLE FOR CURE

Undoubtedly, the most favorable cases for cure are those in which a microscopic diagnosis has been made very early; but in some of these cases I have had rapid local implantation recurrence.

In many cases, one cannot be sure whether fixation of the uterus and induration in the broad ligaments will make a curative operation impossible until one has opened the abdomen, because, in a definite percentage of cases, the fixation and induration may be due to inflammatory conditions and not to cancer; and even

1. Cobb, F.: Cancer of the Uterus, Boston M. & S. J. 167: 37 (July 11) 1912; Cancer of the Uterus, The Possibilities of Cure by the Radical Abdominal Operation, Certain Original Methods of Operating, Including an Analysis of 367 Cases at the Massachusetts General Hospital, *ibid.* 170: 861 (June 4) 1914; The Surgical Treatment of Cancer of the Cervix Uteri, *ibid.* 173: 89 (July 15) 1915.

if due to cancer, a cure may be possible. Frequently, an exploratory incision is all-important in determining the possibilities of a cure, and no man, no matter how large his experience, has a right to condemn a patient without this. The possibility of cure in advanced cases, in which an exploratory incision has determined my course of action, is definitely illustrated by some of my own cured cases.

Marked involvement of the vaginal wall contraindicates a curative operation, as does enlargement of the inguinal glands. If, when the abdomen is opened, the sacral glands are found enlarged, there is no hope of a cure. But enlargement of the iliac and obturator glands does not so contraindicate because these frequently may be enlarged without being cancerous. When palpable, they should be removed. I have removed the iliac and obturator glands in about one half of the cases. In most of the cases, they were not found to be malignant; but in those cases in which they were malignant, a cure has not been obtained. My experience with the lymphatics and small glands in the parametrium, however, is decidedly different; here metastasis takes place very early.

In all cases except those of very early microscopic diagnosis, that is to say, in every case in which there is evident cancer of the cervix, clinically, I use the actual cautery, destroying and sterilizing the cervical portion of the uterus as the first step of one operation in the least advanced and offensive cases; but in the cases of large, fungating disease with foul discharge, I have done this as a separate operative procedure, two weeks or more before the hysterectomy. This double operation I deem wise also with those patients that have lost much blood; in such cases, the period of waiting after the hemostatic cauterization is valuable in restoring strength and hemoglobin. In the last two years, I have abandoned the Percy theory as to the efficacy of a low or moderate degree of heat in using the cautery. In my opinion, this theory is fallacious, the use of the red-hot cautery point to destroy completely the diseased area being the only rational method. I have found also that other forms of the electrogalvanic cautery, soldering irons, or the old Paquelin type of cautery are safer and easier to use than the large instrument devised by Percy, the danger of burns of the vulva, bladder and vagina being much less, even though a water-cooled speculum is used.

AUTHOR'S TECHNIC

The technic of my hysterectomy has not changed in its essentials since my last published paper in 1915. The whole element of success in the operation lies in

the wide removal of the parametrium. Unless this is done, recurrence is almost certain in the lateral areas along the pelvic wall, because, although the iliac and obturator glands are involved late, the lymphatics in the parametrium become cancerous very early, and any operation leaving an infected parametrium is noncurative. There are, in my series of cases, a number in which the iliac glands were enlarged and found non-malignant, but in which a study of the removed parametrium showed cancer. The point of the whole operation is to dissect and isolate so freely the ureters, the bladder and the rectum that a large portion of the parametrium may be removed.

The operation is always long; two hours is a small allowance of time, and in cases that are difficult because of obesity or complicated by pelvic inflammatory disease with adhesions, or in those in which obstinate venous hemorrhage is encountered, much more time will be needed.

The choice of the anesthetic and the employment of a skilled anesthetist are very important. Ether is the anesthetic of choice, but I have used, whenever possible, a combined ether and spinal anesthesia, using a moderate sized intraspinal injection of tropacocain or procain to block off the pelvic operative trauma. After using this method in many cases, I am sure that shock, the chief cause of death in this operation, has been much lessened. Not only has a marked difference been noted in the amount of shock when this method has been used as compared with the cases in which ether alone has been the anesthetic, but also the patients have had much less postoperative disturbance.

The incision has been a median one, extending down to the symphysis pubis and well above the umbilicus. Considerably

more room may be gained by dividing transversely the anterior sheath of the rectus muscles, or in the more difficult cases their tendinous insertions to the pubis. Repair may be rapidly and efficiently done at the end of the operation.

The dissection and handling of the ureters, freeing them completely from the parametrial tissues, is the most important technical part of the operation. The ureters should be so free that they may be lifted up and out of the pelvis, at the same time preserving their blood supply, thus avoiding necrosis and urinary fistula. The use of intra-ureteral bougies is ill advised because unnecessary and time consuming, and it is also dangerous since the bougies prevent free displacement of the ureters. It is my practice to use tapes to lift the ureters up and out of the way, a method described and illustrated in previous papers, by which I feel that the maximum amount of safety may be obtained in dissect-

Fig. 2 (Case 16).—Posterior view of specimen.

ing the vesical end of the ureters, freeing the bladder and rectum, and excising the parametrium. While a reasonable degree of care must be used in handling the ureters, so as not to cause necrosis, they have been in all my cases freely retracted and elevated out of the pelvis, and in none has a urinary fistula from a damaged ureter followed. I have had only two urinary fistulas: in one case, a temporary vaginal leak following a suture of the bladder; and one other, in a case of anastomosis of an accidentally cut ureter. This patient subsequently came to nephrectomy. This freedom from ureteral fistulas, in the light of the reported experience of other operators, has surprised me.

RESULTS IN SIXTY CASES OF RADICAL ABDOMINAL HYSTERECTOMY

Total number of radical hysterectomies	60
Hospital cases	31
Private cases	29
Operated on previous to 1915	35
Operative deaths	7, or 11.6%
Operative deaths in last 30 cases	2, or 6.6%
Number of cases traced	All
Alive and well over 5 years	20
Alive and well over 4 years	3
Alive and well over 3 years	3
Alive and well over 2 years	7
Alive and well over 1 year	2
Summary of operations previous to 1915:	
Total number done over 5 years ago	35
Hospital cases	26
Private cases	9
Operative deaths	5
Recurrences	10
Alive and well over 5 years	20
Percentage of cured cases	57.1

After the ovarian arteries have been ligated, and the broad ligaments opened, the peritoneum being split well above the bifurcation of the iliac arteries, the ureters are exposed lying in their sheaths on the inner or posterior layers of the broad ligaments. The internal iliac arteries are then ligated with catgut, after which the posterior layers of the broad ligaments are incised below and parallel to the ureter, midway between the bifurcation of the iliac arteries and the uterus; and through this slit in the broad ligament, tapes one-half inch wide are passed, traction on which rolls a protecting cuff of peritoneum around the ureters. With such protection, considerable traction can be made safely on the ureter. In cases complicated by inflammatory disease, dissection of the ureters is always more difficult, and the preservation of the broad ligament often impossible; but in such cases, I have had no evil consequences from the use of the tape tractors.

The accidental cutting across of a ureter is a very serious matter, one requiring fine judgment and experience to determine the subsequent procedure in each case. The extra time required to anastomose the severed ends or preferably, when possible, to implant the proximal end in the bladder, may be the cause of death from shock. I have divided the ureter inadvertently twice: one patient died from shock distinctly contributed to by the time required to anastomose the ureter; in the other case, the patient recovered, but the anastomosis was not a success and a urinary fistula and infection of the kidney resulted, necessitating nephrectomy later. This woman is alive and in perfect health today, four years afterward (case of Mrs. F. B., sent me by Dr. MacDougall of Haverhill, Mass., and operated on in 1915). Rather than subject the patient to the extreme added risk of death by taking time for ureteral anastomosis or implantation, one would be justified in ligating both ends of the divided ureter and

staking the recovery of the patient on the functional capacity of the other kidney for the time being.

The most discouraging recurrences are the ones of early implantation metastasis. When such metastasis occurs, one should always suspect faulty technic in amputating the vagina. Necessary precautions against this form of recurrence are the thorough destruction of the diseased cervix by the preliminary use of the cautery, scrupulous disinfection of the vagina with iodine, and use of the double right-angled vaginal clamps and a cautery knife in cutting through the vagina.

After the uterus and upper half of the vagina have been freed from the bladder and rectum, the ureters should be lifted well out of the way by the tapes, and the lateral parametrium from above the internal os, well down the sides of the vagina, should be removed with scissors as close to the pelvic wall as possible. It is at this stage of the operation that one is liable to have trouble with obstinate hemorrhage. I have learned that this part of the operation may well be dreaded as time consuming. After the operation has been completed to all intents and purposes, checking this venous hemorrhage may cause a delay of over half an hour. The use of properly designed right-angled artery clamps is valuable in securing hemostasis deep down in the pelvic hole at this time. Ligation of the internal iliac arteries at an early stage of the operation is a decided help in lessening hemorrhage, and I am certain that it does not in any way increase the chance of postoperative sepsis or sloughing, or cause postoperative cystitis.

Vaginal drainage by a small gauze wick or a cigaret drain has always been used.

A summary of the results obtained in my series of sixty radical abdominal hysterectomies is given in the accompanying table.

419 Boylston Street.

A BENZIDIN-POLYCHROME STAIN FOR BLOOD*

F. A. McJUNKIN, M.D.
MILWAUKEE

For the accurate identification of endothelial leukocytes in blood smears, I have published an earlier report¹ of a staining method employing the so-called "oxydase or peroxidase" reaction. In this method the reagent employed was alphanaphthol, which brings out a blue granulation in the cytoplasm of the reactive leukocytes. Since the granulation is blue, a red nuclear stain was chosen; and the fact that the dilute basic fuchsin solution colors nuclei rather lightly detracts from the value of the stain. A second disadvantage of this earlier method is that the differential coloring of the blood elements in general which has brought the polychrome blood stains (Wright's and others) into universal use is not obtained. The greater accuracy in the identification of the leukocytes secured by the benzidin-polychrome combination, together with the preservation of the blood picture that hematologists now are so accustomed to, will, it is believed, make it of distinct clinical value in the examination of pathologic human blood.

* From the Department of Pathology, Marquette University School of Medicine.

1. McJunkin, F. A.: Differential Blood Count, Arch. Int. Med., 22: 157 (Aug.) 1918.

The method described in this article combines the "oxydase" reaction, which brings out the leukocytic granules, with polychrome staining of the remainder of the blood elements. The method, an account of which was published by Graham,² suggested to me the combination of benzidin and a polychrome stain. For fixation, Graham uses formaldehyd-alcohol, which does not permit of polychrome staining, as the corpuscles retain a deep blue color that cannot be washed out, and the nuclei stain blue. It was found that methyl alcohol of 80 per cent. strength made by adding 5 c.c. of distilled water to 20 c.c. of Merck reagent methyl alcohol, which is about 99.5 per cent. concentration of alcohol, preserves the leukocytic granulation so that smears fixed in it may be stained by Wright's or other polychrome stains, and the success of the benzidin-polychrome stain rests largely on this observation. The only precaution necessary is that the blood smears be allowed to dry for an hour or more before being stained.

BENZIDIN-POLYCHROME STAIN

The method which has now been used in this laboratory for several months on human and animal blood is as follows:

On a 22 mm. square cover glass (No. 1) 4 drops of 80 per cent. methyl alcohol, to 25 c.c. of which there has been added 100 milligrams of benzidin (Merck or that obtained from the Will Corporation) and one drop of hydrogen peroxid, are placed for thirty seconds; this is diluted with 8 drops of distilled water, and the diluted solution is allowed to act for four minutes. The solution is then washed with distilled water and blotted between filter paper; 4 drops of distilled water and 4 drops of polychrome stain (Wright's blood stain) are added, the diluted stain is allowed to act for four minutes, and then it is washed, blotted, dried in the air, and mounted in balsam. All solutions are dropped from similar bottles, with or without a snout-leak, and not from pipets. The benzidin solution keeps for several weeks. The depth of the granule stain is much increased by diluting the benzidin reagent with a phosphate solution having a hydrogen-ion concentration of p_H 6.4 instead of with distilled water. Such a phosphate solution is prepared by adding 63 c.c. of fifteenth-normal (9.078 gm. to the liter) of monobasic potassium phosphate (Merck reagent) to 27 c.c. of fifteenth-normal (11.876 gm. to the liter) dibasic sodium phosphate (Merck reagent). The phosphate solution is also used for diluting the Wright stain. In using the phosphate solution it is necessary to place 2 drops of the benzidin reagent on the cover glass for thirty seconds, dilute with 16 drops of the phosphate solution, and allow the dilution to act for only one minute. Since the amount of reactive substance in the leukocytes of guinea-pig blood is much less than that present in human blood, 8 drops of the phosphate solution are used to dilute 4 drops of the benzidin, and a reaction time of four minutes is allowed in staining the blood of this animal. If the granules are colored too heavily, the structure of the neutrophils and eosinophils is obscured and the dilution with water (or phosphate solution) should be increased and the time shortened. The character of the polychrome stain is important, and a perfect stain must be used. In this laboratory, a sample of polychrome stain had so changed in two weeks at room temperature that it gave very imperfect results.

The granules of the neutrophils, endothelial leukocytes, and eosinophils stain dark brown, while all other blood elements are colored exactly as they are in a simple Wright's stain. The basophilic granules are a rich purple; the large eosinophilic granules are brown and have a ringlike appearance due to their refractive centers; the neutrophilic are dark brown, irregular in

shape, and thickly set in the cytoplasm, while the robin's-egg blue of the lymphocytes is entirely non-granular except for the characteristic "azur" metachromatic granules of a bright reddish color present in some of them. With the uncombined Wright's stain, although the polychrome staining is perfect, there are no positive data regularly present by which to differentiate endothelial leukocytes from lymphocytes, on the one hand, and from those neutrophils that have more or less horseshoe-shaped nuclei, on the other. This disadvantage which attaches to the uncombined Wright's stain is due to the fact that the granulation may not be brought out at all in a certain number of the endothelial leukocytes, in which case they would be mistaken for lymphocytes; and at best the granules are very fine. In the differentiation the nucleus does not deserve the importance so commonly attached to it, since it is perfectly round in some endothelial leukocytes, while in a small number of lymphocytes it shows indentations. In contrast to the results obtained with Wright's and other polychrome stains, which are for these reasons unsatisfactory, the "oxydase" granulation makes identification of the endothelial leukocytes much easier; for in the cytoplasm of these cells there are always distinct discrete dark brown granules. There is no difficulty even with the simpler stains in the identification of the usual neutrophils, for in the endothelial leukocytes there is no filamentous connection of nuclear masses; but in the case of the younger neutrophils in which the nucleus has not become typically lobulated, uncertainties may arise. After application of the "oxydase" reaction, however, the granules in these immature neutrophils are so conspicuous that the separation of these younger neutrophils (metamyelocytes) and the endothelial leukocytes is rather easy. Immature neutrophils are seen to the best advantage in smears of blood from cases of chronic myelogenous leukemia, in which there are many metamyelocytes and in which the younger forms of the bone-marrow cells with their heavy granulations are well brought out.

The differential counting of guinea-pig leukocytes after Wright's staining is more difficult than it is in human blood, and some confusion appears in published classifications of the white cells of this animal. With the benzidin-polychrome stain the guinea-pig leukocytes are found to fall clearly into the same five classes as those of human blood. The brownish neutrophilic granulation is not heavy; and frequently in the endothelial leukocytes there are only three or four distinct brown granules, and these are likely to be grouped together in a focal area in the cytoplasm, especially at the point where the nucleus is indented. The blood of guinea-pigs with an artificially produced endothelial leukocytosis³ shows these peculiarities much better than the blood of the normal animal in which there are few of these leukocytes.

It is necessary that the polychrome stain used be a good one; that is, the chromatin must be colored purple or reddish so that in the lymphocytes the nucleus appears in marked contrast to the blue cytoplasm. During a six months' period this laboratory obtained four samples of Wright's stain, of which two stained well and two gave no chromatin staining manifested by a reddening of the nucleus. After standing two weeks, one of the two faulty samples gave a rather poor polychrome effect. This is the usual experience

2. Graham, G. S.: J. M. Research 39: 15 (Sept.) 1918.

3. McJunkin, F. A.: Experimental Endothelial Leukocytosis in Guinea Pigs, Arch. Int. Med. 24: 295 (Sept.) 1919.

in ordering Wright's, Hasting's, Wilson's, Leishman's and other polychrome stains from commercial sources. In order to have constantly at hand for use in the polychrome-benzidin stain a polychrome solution that is uniform in action, it is advisable to prepare a stock polychrome as described below from which the blood stain may be made as often as desired.

POLYCHROME BLOOD STAIN

I⁴ have described a polychrome blood stain that gives constant results when fresh; but, like the earlier ones, it has been found to deteriorate in a few weeks. Since the publication of this method, the constituents giving the polychrome effect have been found to keep much longer and perhaps permanently in a concentrated glycerin solution, and the stain made in this way has been used in the benzidin-polychrome process, although any good Wright's or other polychrome stain is just as satisfactory. The method of preparing the polychrome blood stain is as follows:

One gm. of methylene blue (Grübler's B. X.), 50 c.c. of decinormal sodium carbonate, 25 c.c. of distilled water, and 25 c.c. of glycerin (Merck reagent) are placed in a 500 c.c. beaker, and heated on asbestos gauze over a low Bunsen flame for one hour at from 87 to 89 C., the ingredients meanwhile being constantly stirred with a mechanical stirrer at the rate of about 120 revolutions per minute. The heating and stirring must be carried out carefully to secure correct polychroming. A mechanical stirrer may be improvised by unscrewing the top from a small electric or water centrifuge, replacing it with a half-inch wooden wheel with a groove for carrying a cord belt, and running the stirrer, with a 2-inch wheel on its top, directly from this. Ten c.c. of distilled water are added at the end of ten, twenty, and thirty minute periods.

At the end of the hour, 5 c.c. of distilled water and 50 c.c. of glycerin (Merck reagent) are added, and the stirring and heating are continued for five minutes; and any dry dye is carefully rubbed from the sides of the beaker into the liquid. There are added 0.75 gm. of eosin (Grübler's yellowish, water soluble) and 0.75 gm. of methylene blue (Grübler's B. X.), and the heating and stirring continued at the same temperature for fifteen minutes. While hot it is poured into a 100 c.c. graduate and made up to exactly 100 c.c. with glycerin, any dye adhering to the sides of the beaker being taken up with the extra glycerin added. It is then poured into a 4-ounce bottle and shaken at intervals for fifteen minutes. Methylene blue and eosin obtained from the Will Corporation, Rochester, N. Y., have given results as satisfactory as those obtained with the Grübler dyes.

The dry dyes are weighed out on analytic balances, and the carbonate solution, which is made decinormal by titration against hydrochloric acid with methyl orange as an indicator, is run in from a buret. All glassware must be free from traces of acid.

From the stock solution prepared in this way, the blood stain is made by adding 3 c.c. with a bulb pipet to 25 c.c. of methyl alcohol (Merck reagent), the alcohol being drawn into the pipet several times to remove the concentrated glycerin solution. All solutions of polychrome stains, except a concentrated glycerin one, change on standing so that the blood stain must be made up from the glycerin stock solution every two or three weeks. In this way it is possible to prepare a polychrome blood stain that has a reaction accurately adjusted and one that can be readily made up in small amounts so as to prevent deterioration. The latter was not accomplished by the method previously

reported. It is possible that the stock glycerin solution may deteriorate after several years, but there is no evidence of change after a six months' period.

To apply the stain to unfixed films, 4 drops of the solution are placed on a 22 mm. cover glass held in suitable forceps, or suitably supported on the top of a small test tube, for one-half minute to fix the preparation. Four drops of distilled water are added, and the stain so diluted is allowed to act for four minutes. It is then washed with distilled water until the film turns uniformly pink. Both stain and distilled water are dropped from bottles and not from a small capillary pipet. A phosphate solution with a hydrogen-ion concentration of p_H 6.4 may be used instead of distilled water for dilution.

Spirochetes and protozoa may be stained heavily by placing the preparations fixed in methyl alcohol for forty-five minutes in a bath made by adding 4 drops of the stock glycerin solution to each cubic centimeter of distilled water. The preparation is removed from the bath, and, after washing out the excess of blue, mounted in the usual way. Cover glasses are floated and slides supported with the preparation side down in such a way as to bring the part to be stained as near to the surface of the liquid as possible. The results obtained compare very favorably with those secured by the Giemsa technic.

DEATH FOLLOWING SPINAL ANESTHESIA

WITH REPORT OF A CASE

JAY IRELAND, M.D.

CHICAGO

Lumbar or spinal anesthesia was first employed by Corning; it was rediscovered and improved by Bier. During the recent epidemic of influenza, there was a need for an anesthetic other than that which might irritate the respiratory passages.

REPORT OF CASE

History.—Mr. C., aged 68, Scotch, a plasterer, entered the ward for nervous patients of the Cook County Hospital, Jan. 15, 1919, complaining of pain in the right side of the chest, eczema of the hands and feet, varicose veins of the legs, and inguinal hernia. The pain in the right chest started, Jan. 10, 1919. It was sharp and stinging, and extended around to the front of the chest at the level of the costal margin. He had had phlebitis in 1901 and 1911, and gonorrhea in 1899, but he denied chancre. He had taken a few drinks of alcoholic liquor a day for the past few years, and had smoked moderately. The family history was negative.

Physical Examination.—The patient was well nourished, not acutely ill, and was mentally normal. The scalp, face, ears, tongue, teeth and pharynx were negative. The pupils were regular and reacted to light and accommodation. No nystagmus was present. The chest was emphysematous; the heart, negative; but the peripheral vessels were sclerosed. The liver was palpable at the costal margin. A large right inguinal hernia was present. Marked varicose veins of the legs were present. Eczema of the hands and feet was present. The reflexes were all normal and present except the abdominals, which were absent.

Clinical Course.—January 19, the pain in the chest, which was diagnosed intercostal neuralgia, disappeared. After lumbar puncture, 3 grains of apothecin were introduced into the spinal canal by the French method (after mixing with spinal fluid) by gravity with the patient in a recumbent position. He was placed in the sitting position, but became

4. McJunkin, F. A.: A Polychrome Stain with Advantages Over the Giemsa, J. A. M. A. 65:2164 (Dec. 18) 1915.

cyanotic. Herniotomy was performed. Four hours later the systolic blood pressure was 98; the diastolic, 62. The pulse was 60 and was very weak. January 22, he was very incoherent and cyanotic, mumbled frequently, and had to be restrained. January 23, he was more stuporous, and involuntary movements occurred; these continued till death. January 24, the right arm was flaccid; and the Babinski, Oppenheim, Gordon, and Chaddock signs were positive on the right. He moved his lips, but made no audible sound. Motor aphasia was present. January 28, the left parotid gland was swollen. January 29, right facial paralysis developed. February 1, slight increased fremitus with crepitant râles was present in the right lower lobe posteriorly. The temperature was 102 F., and respiration was 32. The right pupil was larger than the left; but the fundi were normal. The patient died about six hours after the lung findings began.

Necropsy.—This was performed by Dr. J. P. Simonds, February 3. Findings of sections of the brain, transversely, are:

Section 1 (through the genu of the corpus callosum and anterior tip of the lateral ventricles): There are a few subdymal petechial hemorrhages on both sides. On the left, the corona radiata is soft and grayish; there are petechial hemorrhages in the gray matter of the inferior frontal gyrus; the anterior portion of the island of Reil is dark and red. On the right side, the upper portion of the corona radiata is slightly softer than the adjacent tissues.

Section 2 (through the posterior portion of the septum pellucidum): On the left side, the caudate nucleus is normal. The internal and external capsules and the lenticular nucleus are soft and gray; the corpus callosum is normal in appearance. There is hemorrhage into the superior temporal gyrus; there is an area of hemorrhage into the white matter adjacent to the superior temporal gyrus 0.5 gm. in diameter. On the right side, there are no gross changes of importance.

Section 3 (through the thalamus): On the left side, the internal and external capsules, the lenticular and caudate nuclei, and the corona radiata are soft, and disintegrated, and gray; the superior temporal gyrus is hemorrhagic. On the right side, the superior portion of the internal capsule, the external capsule, and the lenticular nucleus are soft, disintegrated, and gray.

Section 4 (through the splenium of the corpus callosum): Almost all the white matter on both sides is soft, disintegrated, and gray, the condition being somewhat less marked on the right side. Almost all the cortex of the left temporal lobe is soft and dark.

Section 5 (1 cm. posterior to the pulvinar): On the left side, there is hemorrhage with softening about the calcarine fissure and over the posterior portion of the temporal lobe involving the entire thickness of the cortex. The right side shows no gross change.

COMMENT

This case does not present the ordinary findings of cerebral hemorrhage because of the numerous petechial hemorrhages. Houghton¹ states that the higher nerve centers are as a rule unaffected by a spinal anesthetic, and, speaking of stovain, that it seems highly probable with its use as a spinal anesthetic, that its specific action is limited almost exclusively to the locality into which it is injected in moderate doses. The experiments of Barker tend to show that a fluid injected into a tube, the shape of the spinal canal, does not remain in the place where it is injected. Hence some of the fluid injected in spinal anesthesia may travel toward the brain. Bier believes that epinephrin prevents the diffusion toward the brain. Just because a substance in a fluid is heavier than a fluid, it does not follow that this substance will remain where it is placed in the fluid, or at the base of the column of fluid as shown by Barker. Hence it does not follow that apothesis will

remain in the caudal portion of the spinal canal. Houghton states that spinal fluid becomes milky in nature when stovain is added, and microscopically some particles of a milky nature are seen in it, which in a course of time run together into larger globules.

The low blood pressure following operation was in this case probably due to the cerebral hemorrhage. However, Yount,² and Porter and Smith³ state that spinal anesthesia causes fall of blood pressure, and that the amount of fall of blood pressure appears to depend on the amount of drug injected. The manufacturers of apothesis, Parke, Davis & Co., claim that it is less toxic than any other local anesthetic. Eggleston and Hatcher⁴ have shown that in cats, at least, procain is less toxic than apothesis. Bevan⁵ reports using 13½ grains of apothesis at one operation.

Spielemeyer examined the central nervous system of thirteen patients dying after spinal anesthetics. The changes for the most part consisted of degeneration of the motor ganglion cells of the anterior horns, and were seen low down and high up in the cord. In some, the changes were so prominent that they would seem to be irreparable; but none of these changes were found in cases in which the dose did not exceed nine-tenths grain. His experiments with dogs gave the same results. Klost and Vogt's experiments gave the same results. They found chromolysis in some of the anterior motor cells. When physiologic sodium chlorid was used instead of anesthetic solution no changes were observed.

Thompson and Nagel⁶ state that death is probably due to the action of the drug on the vasomotor fibers supplying the splanchnic area. The cause of death in the case herewith presented was due to cerebral hemorrhage. Whether this hemorrhage was due to toxic action of the apothesis on the cerebral vessels cannot be definitely stated. The fact that the blood pressure is lowered by spinal anesthetics would seem to indicate that it was not due to the usual cause of cerebral hemorrhage, i. e., high blood pressure with arteriosclerosis.

The Hospital in a Small Community.—As usual in a small community, the two general hospitals seem to be regarded as competitors. It might seem that the community has work enough for both hospitals to do but, of course, there is room for competition if each seeks to monopolize the profitable patronage of the well to do. What will be the outcome of such rivalry? Will each institution, like a hotel, bid for trade regardless of the actual needs of the community? Will costly equipment be duplicated and high salaried employees multiplied until the cost of good hospital service reaches a maximum limit in both institutions? Or will one hospital, by virtue of its wealth and reputation, attract patients who can pay for the standards of service it maintains, while the other lowers standards as much as it dares, making its bid for patronage on the score of cheapness? And, meanwhile, what will be the fate of that part of the community which makes no demand for hospital care, both because it cannot afford the price and because it has not learned the value?—M. K. Chapin, *Modern Hospital*, December, 1919.

THE MEDICAL RESERVE OFFICER
IN THE WAR *

LOUIS J. HIRSCHMAN, M.D.

DETROIT

So much has been written about the medical reserve officer and his activities in the great war that anything more said may seem to be mere repetition and superfluous. What I shall say will not deal with the scientific aspect of his connection with the army or with the methods of treatment of wounds or diseases incident to military life. I wish to speak in a broad way of the medical reserve officer himself—what he did for the army and what the army did for him. Whatever may be said of a critical nature is brought out merely in the hope that in the reorganization of the Medical Reserve Corps, cognizance may be taken of the errors made in the past with the hope that these may be avoided in the future.

While it is true that services of tremendous value to the soldier were rendered by the medical reserve officer in the cantonments, training camps and hospitals situated in this country, it is not my intention to discuss this phase of the subject, first, because of my personal ignorance of their duties, since my service was overseas, and, secondly, because I wish to discuss only the medical reserve officer's work in the war zone.

In 1908, the original Medical Reserve Corps was organized. Its personnel was selected from among the leaders in the profession throughout the United States. This was done for the purpose of giving the Reserve Corps a high standing because of the high character and professional attainments of the individuals invited to become "charter members" of the corps. After a couple of years, interest was again revived in the Medical Reserve Corps, so that by 1911 a corps of approximately three times the size of the regular army medical corps was organized.

Under limitation by a law in force at that time, all medical officers were commissioned as first lieutenants. After a space of a few years, during which time the medical officers would occasionally receive pamphlets and booklets published by the army, a correspondence course was established, and Medical Reserve Corps officers were invited to take a short course in training camps established throughout the country. A few medical officers accordingly availed themselves of the opportunity to become acquainted with the mysteries of "squads right," "morning sick report" and "service records" and their importance as cogs in the army medical machine.

INEQUALITY OF RANK

When the new bill was made law, abolishing the old corps, making the Medical Reserve Corps a part of the Officers' Reserve Corps, the rank to which a medical officer might be commissioned was raised to that of major. For some strange reason, in every other division of the Officers' Reserve Corps, the maximum rank which a reserve officer could attain was that of colonel. This was an injustice which subsequent events proved to be a severe detriment to the fullest efficiency which officers of the Medical Corps of the highest professional standing in civil life were able to render in service.

It was very soon realized by officers in the Medical Reserve Corps in overseas service that a man's professional ability, experience or attainments were judged, not by his position in the profession in civil life but entirely by the insignia of rank which he wore on his shoulder. In the dealings with medical officers of allied armies and especially with line officers and those of other staff corps of our own, this was too often the rule; and, unfortunately, the American medical officer was often outranked by his professional brothers occupying a similar position with the allied armies.

Those medical reserve officers who responded at once to the nation's call after war was declared, and who accepted whatever commission was given them without question because of their patriotic desire to serve and who went overseas in the spring and summer of 1917, have good cause to remember the penalty imposed on them by the War Department. To be a pioneer proved to be a misdemeanor or crime, because medical reserve officers who blazed the medical trail in France and who had toiled for months in helping to work out our scheme for hospitalization and for the care of the sick and wounded were presently forgotten when promotions were handed out by the powers that be.

Several months after the medical work in France was fairly well organized by the early birds, who were mostly lieutenants and captains and a few majors sprinkled here and there, a crop of newly made majors arrived on the scene. These officers, for the most part, were younger in years and experience than many of the lieutenants and captains in overseas service, and were comfortably enjoying the emoluments and comforts of civil practice while their predecessors had gone overseas and prepared the way for them.

What was our astonishment to find that many of these officers had never heard of the original Medical Reserve Corps. These officers either received their majorities direct from civil life or, after spending from sixty to ninety days in training camps, were rapidly promoted to majors and sent overseas to outrank in many cases their teachers and hospital heads at home.

It was interesting to note that at the early meetings of medical officers in Paris under the auspices of the American Red Cross, there was an absence of service stripes on the sleeves of young officers whose shoulders shone with brand new brightly polished golden oak leaves; while beneath those single and double silver bars of their more mature companions sprouted a goodly number of gold service stripes on the left sleeve and, here and there, a wound stripe on the other.

The first assistant to the chief surgeon of the American Expeditionary Forces, none other than our present Surgeon-General, soon recognized the inequality of rank among his medical reserve officers, and earnestly endeavored to rectify this inequality by recommendations for promotions made toward the end of 1917. For some as yet unexplained reason, the general staff frowned down on any promotions in the Medical Reserve Corps, while they raised the regular army medical officers at least one grade.

In the meantime, promotions up to the grade of brigadier-general were being made in other reserve corps of the army, and the officers so promoted, a few months previously, in civil life, had never heard of the corps in which they were now occupying responsible positions. At the same time, the medical profession

* Read before the Mississippi Valley Medical Association, Louisville, Ky., Oct. 21, 1919.

was furnishing the only reserve officers who had technical training in the department in which they were to serve.

I know of one instance in which the president of a large bank whose only interest in railroad engineering was the possession of large blocks of railroad securities was commissioned as lieutenant-colonel in the engineering corps and rapidly promoted to colonel, later becoming brigadier-general. In the meantime, surgeons whose names were household words in America were serving as captains, in a few cases as majors.

ATTEMPTS AT CORRECTION

It was not until the spring of 1918, nearly a year after some of the reserve officers had begun their service in France that, through the loophole of the National Army, some majors became lieutenant-colonels. The lieutenants and captains, however, without regard to their professional attainments, were still outranked by their interns, assistants and students fresh from home. In spite of all this, let it be said for the medical reserve officers that they kept on doing their duty and attending the sick and wounded, always cherishing the hope that some day conditions would be remedied. The result was that in many hospitals and even in line organizations, lieutenants and captains whose professional and military worth was early recognized were holding responsible administrative positions which, according to the tables of organizations, should have been occupied by officers of field rank. In some of our base hospitals, a captain, and in at least one case a lieutenant, was director in charge of the surgical division; and in one of our famous National Guard divisions, the ranking regimental medical officer for several months, and at the front, was a first lieutenant!

In the spring of 1918, in all other departments of the army, promotions began to appear. The Medical Department, realizing that the position of the pioneer medical reserve officer was unjust and humiliating, endeavored to find some way to remedy the existing conditions. After much thought and many conferences, a wonderful scheme which secured the approval of the general staff was decided on. This was the scheme to promote medical officers, not by the value of their services or of their professional qualifications or of their length of active service, but first and foremost by their age. It was decreed that no matter how valuable a first lieutenant's services might be, if he was unfortunate enough to have been born at so recent a date that he was not 35 years of age, he could not be promoted to a captaincy. Until he had reached the dignity of 40 years of age, no matter how valuable and efficient an officer in the Medical Corps he was, a majority was denied him.

The chief surgeon's office, in an endeavor to get the approval of the general staff on these so-called "corrective" promotions, secured the following concession: For every three months of active service the officer was to receive a year's credit in computing his age for the purposes of promotion. In other words, a lieutenant 33 years of age, who had served six months, would be considered 35 years old for the purpose of promotion to a captaincy. When the first large batch of recommendations for promotions was sent to Washington in July, 1918, however, the actual age was the basis, and not the actual age plus the credit for active service. The names of the officers who did not attain

the actual age required were put on a roster for future promotion which was to include the added credit for actual service. Officers showing exceptional ability or meritorious service were supposed to be exceptions to the general rule. If such exceptional promotions did occur, the majority of medical reserve officers in France and England never heard of them.

UNFORTUNATE RESULTS

Why the reserve medical officer, professionally equipped for his work, was held down arbitrarily by an age limit, while in every other branch of the service the age limit was unheard of, is one of the mysteries of the war on which the medical reserve officer would be pleased to be enlightened.

Many faithful and efficient men were so disappointed by this ruling that their morale was severely affected, and, in spite of themselves, they were not giving their best efforts to their work. The conditions were so intolerable that apologetic and explanatory official circulars were published; in the meantime, however, promotions, except for a few which came through strictly on the age propositions, were slow to come to the medical reserve officer.

It was of the utmost importance that medical officers of high standing in the profession should insure the enforcement of their recommendations. Think of the humiliating position of a leading surgeon of one of our great cities, ranking as a captain, endeavoring to have certain important regulations enforced in a regiment whose colonel in civil life was a merchant who "hadn't much use for doctors."

When rank was needed the most by reserve medical officers, it was denied them by the general staff. Months after the armistice was signed and their relations with medical officers of allied armies and with other officers of our own were on an entirely different plane, then apparently as an act of eleventh-hour repentance, promotions were passed out freely. After the activity of war was over and medical officers were getting impatient awaiting their turns to go home, these belated promotions were not accepted in the spirit which they would have been had they come when higher rank was most needed. On account of the fact that the average practitioner of medicine is not a good business man, many left their families in meager circumstances. When one considers that a practitioner leaving his practice makes a greater sacrifice than the business man who leaves a "going concern" for his assistants to run, the financial part assumes great importance. The difference in salary and commutation between lieutenants' or captains' and field officers' rank meant often the difference between comparative want and comfort for the dear ones at home.

It would be interesting to see the proportion of medical reserve officers who saw overseas service who are now members of the Medical Reserve Corps, as compared with those who refused commissions in the corps. I have listened to conversations between discharged medical officers time and time again, and have found that the feeling of the great majority was that they had been unjustly treated, and that unless the situation was greatly improved, they would hesitate a long time before rushing into service again.

I believe that the "powers that be" at Washington are now commencing to realize that the medical reserve officer was not treated fairly, and I feel that with the

full knowledge of the valuable services rendered by the corps, the reorganization of the Medical Reserve Corps will give the medical officer at least an equal standing with the reserve officer of any other corps of the army.

Our regular army medical corps was, of course, pitifully small at the beginning of the war. Let me say this to the credit of those few men: They had to be spread out very thin in order to form any sort of a backbone to the organization. This meant, of course, that they were all required for headquarters and administrative work and to instruct reserve corps officers. It therefore necessarily followed that all of the professional work, with a very few exceptions early in the war, was done by the reserve corps officers.

The medical reserve officer showed such a marked aptitude for his work that very soon many important administrative positions were likewise filled by reserve officers. The glowing reports of Surgeon-General Ireland testify to the wonderful work done by the medical reserve officers.

From personal observation of the service rendered in front line positions by the reserve officers, I wish to say that patients came back to the field hospitals, in the main, in most excellent condition. The exceptions to this rule were so few that they need practically not be mentioned. In evacuation and base hospital work, medical and surgical teams were composed of men who were leaders at home, and sick and wounded soldiers received a type of professional care that has been seldom surpassed in our leading city hospitals. The casualties among medical reserve officers were high, as were also the citations and awards for individual bravery.

Let it be said to the credit of our profession that, though smarting under the lack of recognition of their work and deserved promotion, they "delivered the goods" in a way that will always remain a tradition to be looked up to by the coming generation. The fact, however, that of 35,000 medical officers in service, a little over 10 per cent. have accepted commissions in the present reserve corps indicates that much missionary work must be done by the officers in charge.

SUGGESTIONS FOR THE BUILDING UP OF AN EFFECTIVE MEDICAL RESERVE CORPS

It is hoped that this subject will be discussed by the members of this association, and that in the discussion will be brought out suggestions which will prove of value to the Surgeon-General's Office in the building up of a reserve corps of excellent personnel and of goodly numbers. Might I make the following suggestions:

1. In order to secure an efficient corps, we have now a wealth of material from which to select its personnel. Approximately 35,000 physicians have seen active service, and a goodly proportion overseas service in the theater of operations. It is proposed, therefore, that all commissions in the Medical Reserve Corps for the next five years be limited to men who have been in active service.

2. Since the Surgeon-General's Office is in possession of data as to the fitness, capability, medicomilitary experience and military adaptability of every medical officer, this information will be of the greatest value in securing the highest type of material for medical officers.

3. Since it is now well recognized that inequality and injustice were frequent in the grading of Medical Reserve Corps officers, particularly in overseas service, it is suggested that all officers be recommissioned in the reorganized corps. Many officers deserve, by the character of their work and the positions they filled, much higher grading than that with which they were discharged. Others were graded notoriously too high for the service they rendered.

4. It is recommended that all applicants for positions who have not seen military service be commissioned as first lieutenants. Since there are so many thousands of officers whose military experience and adaptability are on record, it is obviously unfair to these that a man from civil life should receive higher military commission than one who has shown his worth in active service. Every man in the profession, no matter how prominent he may be professionally or medicopolitically, had his opportunity to do his bit during the war. If he did not, he should take his place at the end of the line if he wants to join the corps at this late date. If all officers start as first lieutenants, they can be promoted as soon as they show that they are qualified to perform the duties of higher grade.

5. In securing professional information and data regarding the qualifications of civilians for commissions in the Medical Reserve Corps, it is hoped that such information will be secured from official rather than personal or political sources. It naturally follows that prospective medical reserve officers should be affiliated with their county medical society, the American Medical Association, hospitals, colleges or universities. From sources such as these, authentic information as to their professional qualifications, personal character and general suitability for the service can be gathered. It is assumed that a hospital in which a man practices his profession will be in a better position to report on his professional ability than will the congressman from his district.

6. As the soldiers of today were the civilians of yesterday, they are subject to the same illnesses and injuries as those of a purely military character. It therefore follows that all the specialties of medicine in civil life should be represented in like proportion in the army. If this had been done in the mobilization camps and recruiting stations, a more thorough system of preliminary examinations would have kept out those soldiers who later on required hospitalization overseas to the exclusion of battle casualties.

7. As different grades in the Medical Reserve Corps are in the same proportion as those in the regular army corps, it is recommended that all of those officers who held commissions who were not called to active duty be honorably discharged. It is well known that while many of these officers were prominent professionally, they were incapacitated for service either by age or unsuitability, and are holding commissions when they cannot possibly serve on active duty. These commissions, if vacated by honorable discharge, would assist in providing higher grades in the Reserve Corps for officers who have refused commissions because they felt they had not been fairly treated.

Let us hope that the Surgeon-General's Office, under its present able leadership, will take cognizance of the unfortunate error of our previous unpreparedness and will build up a Reserve Corps for future emergency which will have as its watchword "efficiency first."

Kresge Medical Building.

HEAT-RESISTANT ORGANISMS

A STUDY OF BACTERIA ENCOUNTERED IN HEAT
STERILIZATION OF SURGICAL LIGATURES
AND SUTURES*

FREDERIC FENDER

ELOISE B. CRAM

AND

PAUL RUDNICK

CHICAGO

We are dealing in this paper only with resistant organisms, which normally occur in commercial, unsterilized ligatures, as they are able to survive the drastic cleaning, bleaching and drying processes through which the raw sheep gut must pass before it becomes a finished ligature or suture.

In the course of the experimentation to determine the temperature necessary to insure sterility of the product, more than a hundred cultures were obtained, both from the raw, unsterilized ligatures and from those heated at various temperatures. These cultures were examined, and from them fourteen typical specimens were selected which included all the varieties observed. From these fourteen cultures five distinct types of bacteria were isolated: three spore-forming bacilli and two cocci. All were aerobic and facultatively anaerobic and grew at both 20 and 37 C., though somewhat more quickly at the latter temperature.

A careful search of the literature failed to disclose any descriptions that would apply to the cocci. The color of their growth on agar, however, indicated that they were saprophytic forms, and this was borne out by the fact that they were nonpathogenic for mice, guinea-pigs and rabbits, the animals showing no bad effects whatever from the injections. It is interesting, also to note the great resistance of these nonspore-forming organisms to extremely high temperatures when the conditions are such as found in the ligatures.

CULTURAL REACTIONS

1. Coccus giving yellow growth on agar:

Morphology.—A gram-positive coccus (from 1.2 to 1.75 microns in diameter) arranged in irregular clusters.

Cultural Reactions.—Agar Slant: A deep yellow, lustrous growth, nonspreading.

Gelatin Colonies: Small, lemon-yellow; under microscope edge entire; finely granular. No liquefaction.

Gelatin Stab: Slight growth on surface; no liquefaction.

Peptone Broth: Heavy turbidity and later a dense sediment.

Sugars: Slight acid production in glucose and saccharose; no gas production.

Pathogenicity.—Negative for rabbits, guinea-pigs and mice.

2. Coccus giving a rose pink growth on agar:

Morphology.—Fairly small gram-negative cocci (from 0.7 to 0.9 micron in diameter) arranged in grapelike clusters resembling staphylococci.

Cultural Reactions.—Agar Slant: Slight rose pink lustrous growth along streak.

Gelatin Colonies: Minute lustrous deep pink colonies. Under microscope, circular shape, highly refractive, brown color. No liquefaction.

Gelatin Stab: No liquefaction; slight growth at puncture. Peptone Broth: An even turbidity, later giving a fairly heavy powdery, orange pink sediment.

Sugars: No gas, no acid production.

Potato: A few minute pink colonies.

Milk: No visible change.

Pathogenicity.—Negative for rabbits, guinea-pigs and mice.

Two of the bacilli were classified according to Lawrence and Ford.¹

3. *B. vulgatus*:

Morphology.—Gram-positive bacilli of medium size (from 1.75 to 3.5 microns by 0.9 micron); ends rather square; spores in center very slightly bulging the sides. Many shadow forms; rotatory motility.

Cultural Reactions.—Agar Slant: Heavy, spreading growth, deep cream color, nonlustrous; wrinkled at bottom and at top; edge uneven. Small round colonies apart from the main growth.

Gelatin Colonies: Small, waxy, cream white colonies; under microscope, highly refractive; edge entire. Rapid liquefaction.

Gelatin Stab: Crateriform liquefaction; scum production.

Peptone Broth: Heavy turbidity, dry, wrinkled white scum. Later an almost complete clearing of the broth.

Sugars: No gas, but acid production in glucose and saccharose.

Potato: Heavy, pink-white, dry, very wrinkled growth.

Milk: No acid production or coagulation; pronounced peptonization.

Pathogenicity.—Negative for rabbits, guinea-pigs and mice.

4. *B. simplex*:

Morphology.—Gram-positive slender rods (from 3.5 by 0.58 to 0.87 micron) growing out in long filaments (from 14 to 17.5 microns), especially in glucose broth. The spores occur in the short rods and do not swell the sides. Very actively motile.

Cultural Reactions.—Agar Slant: Thin, transparent, cream colored growth.

Gelatin Colonies: Thin, white colonies, lustrous; edge entire.

Gelatin Stab: Cup shape liquefaction; no visible growth.

Peptone Broth: Even, faint turbidity.

Sugars: No gas, no acid production.

Potato: Heavy, moist, cream yellow, spreading growth.

Milk: No coagulation; pronounced peptonization.

Pathogenicity.—Negative for guinea-pigs.

5. *Bacillus*: This bacillus did not conform to any of the aerobic, spore-bearing, nonpathogenic bacteria classified by Lawrence and Ford, but its morphologic and cultural characteristics closely resemble those of *B. lacteus* as described by Chester.²

Morphology.—Gram-positive bacillus (3.5 microns by 0.9 micron in size), occurring in chains; spores developing at end, swelling the sides. Motility negative.

Cultural Reactions.—Agar Slant: Medium heavy, gray white, nonlustrous, moist growth; edge undulate; wrinkled at bottom.

Gelatin Colonies: No visible colonies in from two to ten days; no liquefaction.

Gelatin Stab: Slight liquefaction over entire surface.

Peptone Broth: Tenacious scum, smooth surface; when shaken, scum gives off heavy flocculi into broth.

Sugars: Acid production in glucose. No gas.

Potato: Fairly heavy, moist, nonlustrous, cream colored growth; uneven edge.

Milk: Decolorized; coagulation and peptonization.

Pathogenicity.—Negative for rabbits, guinea-pigs and mice.

A twenty-four hour broth culture showing heavy growth was used for the animal injections; 0.2 c.c. injected intravenously in rabbits, 0.5 c.c. intramuscularly in guinea-pigs and 0.3 c.c. subcutaneously in mice.

Before surgical ligatures can be sterilized, it is necessary to remove all moisture from them in order to prevent hydrolysis. If this is not done, the application of heat readily converts the collagen of the ligatures into gelatin, thereby destroying or at least seriously injuring their tensile strength. Sterility must, consequently, be produced by dry sterilization. Fractional sterilization is of no avail, since the spores are unable to develop in the absence of water. Mercuric iodid and other radical germicides, even in solution, have little or no germicidal value in the absence of water. The tanning and chromacizing processes do not in the least inconvenience the resistant organisms found in ligatures, nor does vacuum drying for six hours at from 90 to 95 C. Chloroform does not destroy these organisms and spores, even after heating in sealed tubes at 125 C. for one and one-half hours. They are also indifferent to petroleum benzin, kerosene, carbon tetrachlorid, toluene, xylene and similar liquids at the above mentioned temperature.

The only effective means of producing sterility in plain and chronic ligatures is by the application of heat. This may be accomplished by heating the ligatures in oil or some other suitable, nonaqueous liquid to the desired temperature, as originally suggested by Bartlett.³ This temperature must be sufficiently high to destroy all living protoplasm, and it must at the same time be below the decomposition temperature of the ligature proteins in order to avoid destruction of the ligatures. Practical experience has demonstrated that such a margin exists, although its limits are rather narrow.

Absolute sterility is assured by heating the ligatures gradually up to 160 C. and maintaining this temperature for one hour. This confirms Bartlett's findings.³ Numerous tests have demonstrated that heating at 150 C. for one hour or at 140 C. for three hours does not always produce sterility. This applies to the cocci as well as to the spore formers described in this paper. These temperatures weaken or stunt the organisms and spores to such an extent that growths do not appear until the fourth, fifth or even sixth day of incubation, a point of considerable importance in the control examination of ligatures.

The thermometers employed were certified by the U. S. Bureau of Standards.

CONCLUSIONS

1. Of five distinct types of heat-resisting bacteria described, including both cocci and bacilli, which commonly occur in raw ligatures and sutures, none were found to be pathogenic.

2. Plain and chromicized ligatures and sutures can be sterilized only by heat. Antiseptics and germicides are of no value in the absence of water.

3. The thermal death point for the five types of bacteria lies between 150 and 160 C. under the conditions found in ligatures and in nonaqueous liquids.

4. Absolute sterility is assured by gradually heating the ligatures in oil or some other suitable nonaqueous liquid up to 160 C. and maintaining this temperature for one hour.

5. The great resistance to heat of the two types of cocci described is a very important fact.

ACUTE METHYL ALCOHOL POISONING ASSOCIATED WITH ACIDOSIS

REPORT OF CASE *

GEORGE A. HARROP, JR., M.D.

AND

E. M. BENEDICT

BALTIMORE

Ever since its introduction into commerce, methyl alcohol has been the prolific cause of a severe and frequently fatal type of poisoning. The recent increase in the number of cases reported, due to various preparations which have this alcohol as their basis and which have resulted in blindness or death, has indicated the possibility that the condition will assume still greater importance with the more rigid enforcement of the national prohibition amendment. It seems desirable to report the following case, together with the collected data, because it appears to offer a suggestion as to therapy, hitherto disregarded.

A brief summary of the clinical history follows:

REPORT OF CASE

History.—C. B. (Medical No. 137328), woman, aged 25, white, actress, admitted, Nov. 24, 1919, discharged, December 23, with irrelevant previous history, on the night of November 22 drank about half a pint of a fluid supposed to be brandy. Subsequent examination by a chemist of the small amount available for analysis indicated that 87 per cent. of the alcohol content was methyl alcohol.

The following afternoon (November 23), the patient felt weak and nauseated. On the morning of the 24th she vomited, and began to notice dimness of vision, which rapidly increased. She had pain in her back, headache, marked thirst, and considerable difficulty in breathing. Late in the afternoon she was seen by a physician, who had her removed to the hospital.

Physical Examination.—On admission the patient was drowsy and cyanotic, her breathing was deep and rapid, she was restless, and she complained that everything looked black in front of her. The temperature was subnormal. The pupils were dilated, but reacted to light. No particular odor was noted on the breath. Gastric lavage was done, and alkali was given by mouth, but it was not retained. The air hunger rapidly grew more marked, and about midnight the bicarbonate content of the blood plasma (Van Slyke) was equivalent to 36.4 per cent. by volume of carbon dioxide. The patient was then given 400 c.c. of 5 per cent. sodium bicarbonate solution intravenously.

November 25, her vision was practically gone. She was still nauseated, and although the hyperpnea was much less marked, the determination of the plasma bicarbonate still indicated a marked acidosis, and a second intravenous injection was given of 500 c.c. of 5 per cent. sodium bicarbonate. Thereafter there was no evidence of acidosis as indicated by the plasma bicarbonate. The clinical examination of the blood, spinal fluid and urine revealed nothing of diagnostic significance.

During the following two or three days she exhibited a rather marked delirium with visual hallucinations. Thereafter she was quite normal mentally. The vision improved gradually, but a well-defined central scotoma remained on the left side, and there was evidence on ophthalmoscopic examination of a mild postneuritic atrophy on the left.

The accompanying table shows the chemical studies made. There was at no time a disturbance of the phenolsulphonephthalein excretion or of the normal blood urea concentration. The acetone bodies were determined by the method of Van Slyke.¹ The titrable organic acids in the urine were

3. Bartlett, Willard, cited by Beckman, E. H.: Operating-Room Technique, Collected Papers by the Staff of St. Mary's Hospital, Mayo Clinic, 1905-1909, Philadelphia, W. B. Saunders Company, 1911, p. 586.

estimated by the method of Palmer and Van Slyke.² The formic acid in the urine was determined by the method of Dakin, Janney and Wakeman.³ The lactic acid in the urine was estimated by a modification of the Ryffel⁴ method. It was impossible to obtain accurate total collection of the urine during the first days on account of the patient's condition, so that the total excretion of the several factors studied could not be determined. The creatin and creatinin determinations were done by Folin's method, while the inorganic phosphates of the blood serum were estimated by Marriott's method.

As is indicated, the patient was admitted with an acidosis of a severe grade, which promptly disappeared following the intravenous use of sodium bicarbonate.

COMMENT

It was pointed out long ago that, whereas ethyl alcohol is completely oxidized with ease by the animal metabolism, such is not the case with methyl alcohol; and Pohl⁵ in 1893 showed that formic acid, a normal constituent of the urine, is excreted in greatly increased quantities following the administration of this alcohol to dogs by mouth. He found that the formic acid was excreted very slowly, and that the maximum amount of formates was not present in the urine until the third or fourth day. The total amount so excreted

hand, Bongers⁷ asserts that considerable quantities are thus disposed of.

Acting on a suggestion of Schmiedeberg's,⁸ that an acidosis might be produced in cases of methyl alcohol poisoning, on account of the formation of formic acid, Król⁹ was able to show a well-defined increase in the ammonia of the urine associated with the increased formic acid excretion in dogs. The formic acid excreted, however, accounted for only about one quarter of the ammonia. Król did not attempt to determine what acid might account for the major part of the ammonia, except that he states that it was not oxalic acid.

On the basis of somewhat crude methods, Tyson and Schoenberg¹⁰ concluded that they could produce an acidosis in rabbits following the inhalation of methyl alcohol. They considered methyl alcohol to be a "true hemotoxic," and their plan of treatment, "based on the findings, might be summed up in two words: eliminate and stimulate." Authors have generally ignored the specific indications for the treatment of the acidosis as such.

The description of the clinical findings in the large group poisoned at Christmas, 1911, in Berlin states that

by no means accounted for the entire dose given, and the maximum recovered after the feeding of sodium formate itself, which is quickly excreted, was but 18 per cent.

One experiment was made on a man who drank 25 c.c. of methyl alcohol, which caused similarly a marked rise in the formate excretion.

The fate of the remaining portion of the alcohol is not known. A considerable quantity can be recovered, according to Asser,⁶ in the expired air. Thus, he was able to recover, over a period of seven days following its administration, 55.8 per cent. of 25 c.c. of methyl alcohol given by mouth to a dog, while in the urine following such a dose he recovered only from 3.1 to 4.6 gm. of formates. This author has made the further interesting observation that when ethyl or amyl alcohol, or acetone, is given together with the methyl alcohol, the excretion of the formates is very appreciably diminished over the amount recoverable when methyl alcohol is given alone. As to the excretion of methyl alcohol itself in the urine, there is some disagreement. Pohl did not recover it but, on the other

in the most severe cases the patients had marked cyanosis and severe air hunger.¹¹ Many references can be found, in clinical reports, of respiratory distress and of forced breathing, in the severer cases, which may well have been the hyperpnea of acidosis.

The marked increase in the lactic acid excretion, together with the rise in the urinary creatin (which was far greater than could be accounted for simply by starvation), makes it evident that we are dealing with a more profound disturbance of the metabolism than is indicated by the simple failure of the body properly to oxidize the methyl alcohol. It would appear, however, that when an acidosis is demonstrated by the proper laboratory tests,¹² the employment of the usual therapy, particularly the administration of sodium bicarbonate, is urgently indicated. We feel convinced that a definite therapeutic aid was in all likelihood obtained by its use here. Certainly, so far as the formic acid is concerned, the excretion is limited by the amount of the

alcohol ingested, and more is to be expected as a result of its prompt neutralization than in other types of acidosis, in which the formation of acid metabolites may continue quite independently of our ability to neutralize them.

Of practical importance is the observation of Bongers,⁷ who gave methyl alcohol to dogs by mouth, and then estimated the amounts recoverable by gastric lavage repeated over several days. He asserts that he recovered about three times as much methyl alcohol in the combined washings of the second and third days as he was able to obtain in those of the first. He was also able to recover formic acid in the stomach washings twenty-seven hours after the alcohol was given. This work would appear to point out clearly the importance of thorough and repeated lavage.

SUMMARY

1. In case of severe acute poisoning with methyl alcohol, associated with a marked grade of acidosis, recovery followed the use of alkali therapy.

2. The acidosis was associated with an increase in the amount of titrable organic acids in the urine, and specifically with a marked increase in the excretion of lactic and of formic acids.

3. The acidosis, when present, furnishes an indication for the use of prompt therapeutic measures.

4. On the basis of the work quoted, it is submitted that gastric lavage should probably be done over a period of several days.

CULTURAL STUDIES ON A CASE OF SPRUE

PRELIMINARY NOTE *

WADE W. OLIVER, M.D.

BROOKLYN

The purpose of this preliminary communication is to record briefly certain laboratory findings in a case of sprue.

REPORT OF CASE

Charles W., an American, resident in Porto Rico, invalided north, was admitted to the Long Island College Hospital, where stool cultures were made. Following this, tongue cultures, sputum cultures and a culture from a tooth abscess were taken, as well as a blood culture. On two occasions from the stool, twice from tongue scrapings, once from the sputum and once from the tooth abscess, a growth of yeasts was obtained which corresponded in the main to *Monilia psilosis*, described by Ashford¹ as the cause of sprue.

Isolation of Organism.—In the case of the stool, cultures were obtained by emulsifying a standard loopful of stool in from 1 to 2 c.c. of sterile physiologic sodium chlorid solution and streaking from 1 to 2 loopfuls of the suspension across large (135 mm.) + 1 glucose agar plates which had previously been allowed to harden. Cultures from the tongue were taken in one case by scraping the inflamed tongue with a sterile knife, after preliminary swabbing of the tongue with sterile water, and in the other instance by thoroughly swabbing the tongue with a sterile cotton swab. In both instances, *Monilia* was isolated when a large + 1 glucose agar plate was streaked, and the culture incubated at 37.5 C. (99.5 F.). A positive culture was obtained from the tooth abscess by inserting into the latter a small sterile pledget of cotton mounted on a sterile stick and immediately streaking several large plates of

+ 1 glucose agar. From the sputum, which was lightly streaked with blood, cultures were secured by thoroughly washing a small fragment of bloody sputum in several tubes of sterile physiologic sodium chlorid solution and then streaking the fragment over three large 1 per cent. glucose agar plates (+ 1). The plates were incubated at 37 C. (98.6 F.). A blood culture was negative, and after two weeks' continuous incubation at body temperature, the + 1 glucose blood agar plates and the + 1 glucose blood broth were discarded.

Morphology.—The yeast exhibited quite a striking variation in size and form, which seemed somewhat independent of the medium, as a mount made from a single colony showed a polymorphism among its members. The single cells were round or oval, varying in diameter from about 2 to 7 microns, were sharply defined in outline, and possessed a nucleus which was recognizable in fresh preparations. Many cells showed an oval or spherical, faintly outlined vacuole. Mycelial elements were occasionally observed in + 1 glucose agar but best apparently in gelatin.

On + 1 glucose agar plates incubated at 37 C. for two days, the colonies of *Monilia* were white, glistening, elevated, and soft, with clearly defined borders. In cultures, a rather "yeasty" odor was observed. In + 1 infusion broth, at the end of twenty-four hours at 37 C., the broth was evenly clouded. Broth cultures incubated for three or four days or longer usually exhibited a sedimented growth at the bottom and a white growth ring at the surface of the medium where it was in contact with the glass.

In gelatin stab cultures, the growth resembled that of an inverted pine tree. Smears made from the growth in gelatin showed considerable numbers of mycelial elements, which varied in size and usually were somewhat wavy in outline.

Fermentation Tests.—Fermentation tests were made by the Durham tube-within-a-tube method. The medium employed was peptone water in which the respective sugars were present in a concentration of 1 per cent. The Andrade indicator was used to determine acid production. Readings were made daily, and the tubes were incubated for at least two weeks at 37 C. before they were discarded. The material used for inoculation was taken from twenty-four hour + 1 glucose agar slants. Between thirty-six and forty-eight hours' incubation was found to give the optimum acid and gas readings. In the tests herewith recorded, sugars that were not fermented within this time failed to be fermented on longer incubation, nor did transplants made from such sugars to respective sugar broths incubated at 37 C. for two weeks result in fermentation. From the table of fermentation tests, it is to be noted that the stool and tongue strains agree in their acid producing power, but that the tongue strain produces both acid and gas in saccharose, whereas the stool strain splits off acid alone from this disaccharid.

RESULTS OF FERMENTATION TESTS

Medium	<i>Monilia</i> from Stool	<i>Monilia</i> from Tongue Scrapings
Glucose	Acid +; gas @ 90%	Acid +; gas 100%
Levulose	Acid +; no gas	Acid; no gas
Galaetose	Acid; no gas	Acid; no gas
Saccharose	Acid (faint); no gas	Acid +; gas @ 80%
Maltose	Acid; no gas	Acid; no gas
Lactose	No acid; no gas	No acid; no gas
Mannite	No acid, no gas	No acid; no gas
Dextrin	Acid (very faint); no gas	Acid (faint); no gas
Xylose	No acid; no gas	No acid; no gas
Inulin	No acid; no gas	No acid; no gas
Glycerin	No acid; no gas	No acid; no gas

Animal Inoculations.—Two standard platinum loopfuls of a twenty-four hour + 1 glucose agar slant culture suspended in 0.5 c.c. of sterile physiologic sodium chlorid solution were injected intraperitoneally into a guinea-pig weighing about 250 gm. Twenty-four hours after inoculation a lump about the size of the little finger nail was easily palpable in the abdomen at the site of inoculation. The guinea-pig, after the first day, refused to eat, and died on the seventh day after inoculation. At postmortem, a rather discrete, large abscess was found subcutaneously around the site of inoculation. The abscess extended into the peritoneal cavity and involved the omentum, spleen, colon and the lower lobe of the liver. Scattered, small discrete abscesses were also found on the under surface of the

* From the Department of Bacteriology, Hoagland Laboratory, Long Island College Hospital.

1. Ashford, B. K.: Etiology of Sprue, Am. J. M. Sc. 154: 157 (Aug.) 1917.

colon and in the liver. The gallbladder was dilated, the fluid increased in amount, hemorrhagic, and contained a large white mass resembling a colony of yeasts. From the gallbladder, as well as from a liver abscess, *Monilia* was recovered in culture, mixed with *Staphylococcus aureus*.

SUMMARY

From this case of sprue, a yeast was recovered which corresponds in the main to *Monilia* of Ashford. It is perhaps somewhat of interest because there are few recorded cases of sprue studied in temperate climates from an etiologic standpoint.

The organism was isolated on +1 glucose agar plates from the stool, tongue, sputum and a tooth abscess.

Intraperitoneal injection of a guinea-pig killed the animal in seven days, and from the liver and gallbladder, the yeast was recovered, mixed with *Staphylococcus aureus*.

Henry and Pacific Streets.

Clinical Notes, Suggestions, and New Instruments

A NEW STAIN FOR DIPHTHERIA BACILLI*

HENRY ALBERT, M.D., IOWA CITY

The report of one or several "new" stains for diphtheria bacilli almost every year since 1895 would seem to indicate that none of those previously recommended have been entirely satisfactory.

I have tried practically every stain heretofore described. A rather critical review of these will appear before long in the *American Journal of Public Health*.

My purpose here is to make available the formula for a new method of staining diphtheria bacilli which I have developed and which my associates and I have found to be more satisfactory than any stain heretofore described. Two solutions are used:

SOLUTION 1	
Toluidin blue	0.15 gm.
Acetic acid (glacial)	1.00 c.c.
Alcohol (95 per cent.)	2.00 c.c.
Water (distilled)	100.00 c.c.

Solution 2 is the same as the iodine solution used in the Gram stain:

SOLUTION 2	
Iodin	1 gm.
Potassium iodid	2 gm.
Water (distilled)	300 c.c.

TECHNIC OF STAINING

Smears are made on slides or cover glasses in the usual manner, fixed by heat, and stained with toluidin blue solution for five minutes. The stain is then drained off without washing, and the iodine solution applied for one minute. It is then briefly washed with water and dried, preferably by means of filter paper. It is now ready for examination.

Occasional lots of toluidin blue stain the diphtheria too uniformly. One that stains the granules well should be selected.

If staining is done in staining dishes, the iodine solution should be replaced with a fresh supply daily, since a precipitate results from the introduction of the toluidin blue stain carried over on the slide.

MICROSCOPIC PICTURE

The granules of the diphtheria bacilli are stained black—standing out in marked contrast to other elements in the microscopic field. The bars of the bacilli take a color varying from dark green to black; and the intermediate portions, as well as other bacteria, take a light green.

The granules of diphtheria bacilli stand out very much more prominently than they do when stained by Loeffler's methylene blue and other stains that are commonly employed. The bars stain with varying intensity. Sometimes they stand out better, sometimes not so well as with the Loeffler stain. They are, however, easily recognized. In this respect it is much better than certain stains, such as the Neisser, which sometimes stain the granules very well.

ADVANTAGES

1. Diphtheria bacilli are more readily recognized by virtue of the fact that the granules of the bacilli stand out in very sharp contrast to other portions of the bacillus and more especially to other bacteria which are but feebly stained.

2. Diphtheria bacilli may be recognized in younger cultures, and hence the diagnosis made earlier.

3. The bacilli may be seen equally well by daylight and artificial light.

4. The results of staining are uniformly good.

STEREOSCOPIC ROENTGENOGRAPHY WITH THE BEDSIDE UNIT*

HOWARD CURL, M.D., MADISON, WIS.

With the development by Dr. Coolidge of the self-rectifying roentgen-ray tube and the portable transformer, and the subsequent production of large numbers of these completed units, a long felt want has been realized.

Designed especially as a portable unit for bedside use in hospitals, they are nevertheless capable of handling a large part of the work that comes to the general practitioner. This fact, together with the low cost, ease of installation, and simplicity of operation, will mean that many of these units will soon be in the hands of the profession.

There is, however, one very important feature which until now the designers have apparently overlooked, and that is a means for shifting the tube for stereoscopic plates. The man accustomed to stereoscopy will feel this loss keenly, and the physician who has not yet learned to use stereoscopic roentgenography in his roentgenographic examinations should know that the difference between a single plate and

Fig. 1.—Tube stand built into unit.

a pair of stereoscopic plates is often the difference between failure and success in making a diagnosis. Especially is this true in regions about the hip or shoulder joint where it is impossible to obtain a two-way view.

Stereoscopic plates may be obtained with the bedside unit (1) by using a regular stereoscopic tube stand, or (2) by adapting the stand which is built into the unit to this type of work. The second method, besides being cheaper, eliminates the use of a second piece of apparatus. It is my purpose in this article to suggest a simple means of converting the unit tube stand into one that is suitable for stereoscopy.

Figure 1 illustrates the tube stand built into the unit: a, upright stand; c, horizontal sleeve, supporting extension

* Brief description of a stain described before the Laboratory Section of the American Public Health Association at New Orleans, Oct. 26, 1919.

* From the Department of Clinical Medicine, University of Wisconsin Medical School.

arm *c*; *f*, screw for holding extension arm at any given setting; *d*, holder for self-rectifying tube, and *g*, wire cable passing over pulley to counter weight.

To obtain stereoscopic plates the extension arm was marked with circular grooves (Fig. 2, 6) at 6-cm. intervals. On this arm was also placed a sliding collar (5). The tube is adjusted over the patient with one of the circular markings on *c* flush with the end of the sleeve. The collar is set at 6-cm. distance, which will be at the next mark. The first

Fig. 2.—Adjustment for obtaining stereoscopic plates.

plate is taken, the tube is slid in as far as the collar will permit, and the second plate is taken. Care must be taken in shifting the tube to see that the tube does not rotate, i. e., that the same angle is preserved for the second plate. To eliminate this danger, we added two auxiliary sleeves (1, 1),

Fig. 3.—Plate changing tunnel.

parallel to *c* supported on it by two circular bands (2, 2). Two auxiliary rods (4, 4) fit into the sleeves. The tube may now be rotated to any angle and held by screw 3, screw *f* being no longer needed.

Thus, we have a tube stand with a horizontal displacement of several inches, a means for obtaining the regulation 6-cm. shift for stereoscopic plates, and a device for holding the tube at any desired angle while making the shift. With the aid of a plate changing tunnel, Figure 3, stereoscopic plates of any part of the body may be made at the bedside with a minimum of discomfort to the patient. This will be of especial value in fractures of the leg, femur or hip joint when the part is up in extension, and of which a two-way view would be difficult or impossible to obtain.

Tuberculosis in the Malay States.—Dr. J. T. Clarke, health officer of Kinta, has collected evidence in support of his thesis that the "massive dose" of tubercle bacilli is the all important factor in the causation of phthisis. He notes, as rather remarkable, that there is a higher proportion of phthisis among Chinese males than females in Singapore, the proportion being 6.04 to 3.81. But if all cases of phthisis, bronchitis and pneumonia be classed together, the difference is much less, the proportion being 8.99 males to 8.1 females. Bovine tuberculosis does not exist in the Malay Peninsula; no case of tubercle in a domestic animal has been discovered, and among more than 250,000 pigs killed in the Ipoh abattoirs during the last four years, there was no case of tuberculosis. The disease in man must, therefore, be exclusively due to infection from human sources. In Singapore, phthisis causes 16 per cent. of the total deaths. Discussing von Behring's theory of infection, which he rejects, Dr. Clarke observes that the Chinese seldom take milk, even as children, and that in the straits settlements the cattle are at present free from tuberculosis.—*Lancet*, Nov. 29, 1919.

AND OTHER REMEDIES IN THE TREATMENT OF DISEASE.

USE AND ABUSE OF CATHARTICS*

(Continued from page 1939)

PHENOLPHTHALEIN

About twenty years ago the Hungarian government decreed that wine, adulterated by certain harmless additions, be earmarked by means of phenolphthalein, because of the property of this substance of assuming a brilliant red color on addition of alkali, and of its supposed harmlessness. This was done with the intention of enabling the poor man to buy this "necessity of life" at a price within his reach. But it was soon found that people partaking freely of this wine suffered from diarrhea, which at one and the same time led to a hasty repeal of the law and the discovery of a new purgative.

This recent addition to the cumbersome list of cathartics is of interest only because of the fact that it is almost tasteless and is active in small doses. It lends itself admirably to palatable administration, even to being given in the form of bonbons, which makes it especially suitable for children and for the insane; though women generally and even men prefer it on account of the inoffensiveness of its taste.

It is a yellowish-white powder, odorless and almost tasteless, very slightly soluble in water, and soluble in alcohol (13 parts) and in aqueous solutions of alkalis, yielding a pink fluid. It is also soluble in olive oil to the extent of about 2 per cent.

Being insoluble in acids, it passes through the stomach unchanged; hence it may be given in conditions of gastric irritation when many other cathartics would be contraindicated. On reaching the intestine, it is partially dissolved in the alkaline secretions, becoming converted into salts which are irritant, and thus becoming active. Very little is absorbed; more than 85 per cent. of it has been found unchanged in the feces. After large doses, however, traces are found in the urine, which then turns pink when rendered alkaline by decomposition or otherwise. That it does not irritate the kidney is shown by the fact that subcutaneous injection of a very similar substance—phenolsulphonephthalein—has become an accepted test for the functional capacity of the kidney. There are no known systemic effects produced after absorption.

Phenolphthalein probably acts chiefly by influence on peristalsis; in other words, it belongs among such drugs as cascara sagrada and senna, so far as mode of action is concerned. It is even effective as a cathartic when given subcutaneously, though Abel and Rowntree¹ found phenoltetrachlorphthalein (0.4 gm. in 20 c.c. of oil) superior for this purpose.

The chief disadvantage of phenolphthalein is a certain degree of variability of action. At times, a small dose acts excessively; at times, a larger dose fails to act. An overdose, and in especially susceptible persons even a therapeutic dose, may cause, in addition to free

* This is the twelfth of a series of articles on the pharmacology, physiology and practical application of the common laxatives and cathartics. The first article appeared October 18.

1. Abel and Rowntree: *J. Pharmacol. & Exper. Therap.* 1:231 (Aug.) 1909.

purgation and colic, rapid pulse, palpitation, difficult breathing and general uneasiness, even collapse. The substance is otherwise quite free from toxic tendency. Doses of several grams have been tolerated without more severe effects than those just detailed. There are no fatal cases on record.

It should be borne in mind that phenolphthalein may cause reddish stools, when the reaction of the evacuation is alkaline, or is made so by a soap enema, for instance. Under such circumstances, the suspicion may arise that there is blood in the stools. Of course, the diagnosis can readily be made by the fact that acidification removes the color, which reappears when excess of alkali is added. In view of the frequency with which this drug is now being used, we must beware of making a diagnosis of blood in the stools by mere inspection.

The dose of phenolphthalein for adults is from 0.10 to 0.20 gm. (1½ to 3 grains). The U. S. Pharmacopeia states that the average dose is 0.15 gm., or 2½ grains. As little as 0.06 gm. (1 grain) is often sufficient for an adult, and this dose is none too large for a child. Babies aged 18 months are given 0.03 gm. (one-half grain). In obstinate cases, as for instance bed-ridden patients, from 0.5 to 1.0 gm. (8 to 15 grains) may be given without fear. It will be noted that, on the whole, the dose of this drug is quite independent of age. It is also true that at any age the effect is somewhat independent of dose. Evidently the activity depends on the amount of alkali in the intestine available for solution; and it is probable that variation in intestinal reaction accounts for the variability in intensity of action.

As phenolphthalein is a comparatively slowly acting drug, requiring from six to twelve hours for effect, it is generally given at bedtime. While, when large doses are needed, these would best be prescribed in powder form, the usual method of administration for the ordinary dose is in the form of sweet tablets to be eaten like candy. The National Formulary contains a formula for pink, vanilla flavored *troches of phenolphthalein*, each containing 0.06 gm. (1 grain) of the drug. These are made with acacia, and therefore disintegrate rather slowly. This is undesirable. Lozenges made in this way are suitable for mouth and throat medication; more rapid disintegration is desirable in candy medication for systemic action, as sick children sometimes refuse to suck candies that healthy children would enjoy. Friable tablets can be obtained by light compression in a tablet machine. The following formula² will yield such a product, which can be prepared extemporaneously by a pharmacist equipped with a tablet machine. Without compression into tablets the same formula yields a palatable powder.

SWEET TABLETS OF PHENOLPHTHALEIN, 0.06 GM. EACH

Phenolphthalein	6.00 gm.
Saccharin	0.12 gm.
Tincture of vanilla	1.50 c.c.
Cacao powder	3.00 gm.
Sugar, powdered	21.00 gm.

Mix the saccharin with the tincture of vanilla and incorporate the phenolphthalein. Finally add the sugar and the cacao by thorough trituration in a mortar. Compress in a tablet machine, using ⅜-inch die and punches, to make 100 0.30 gm. tablets.

All the various manufacturing houses of pharmaceuticals put up fairly acceptable sweet tablets con-

taining 0.06 gm. each and up to 0.30 gm. Such tablets might simply be prescribed for as follows:

R 12 Sweet tablets of phenolphthalein, 0.06 gm. (1 grain) each
Label: One or two at bedtime.

For infants, sweet tablets might be crushed and given in a little water.

The novelty and the inoffensiveness of this remedy has rendered it an inviting object for commercial exploitation. Soon after its introduction, the market became literally flooded with phenolphthalein in various disguises and combinations, the only original feature of most of which was a coined name. The following is a partial list of names under which phenolphthalein preparations and combinations are or were advertised:

Allophen, Cholelith Pills, Elzernac, Ex Lax, Exurgine, Laxophen, Laxine, Laxirconfect, Laxothalen Tablets,	Paraphthalein, Phenalein, Phenolax Wafers, Phenolphthalein Laxative, Probilin, Prunoids, Purgatol, Purgen Konfect, Purgella,	Purglets, Purgo, Purgolade, Purgotin, Purgylum, Rhuphen, Thalosen, Veracolate, Zam Zam.
--	--	---

What a Babeldom would arise in medical practice if this business policy of manufacturers to protect their product by coined names were encouraged by the patronage of physicians. Self-respecting manufacturers owe it to the progress of medical science to do away with such camouflage for revenue only; and the medical profession owes recognition to these manufacturers by prescribing products by their scientific names.

(To be continued)

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

SULPHOICHTHYOLATE PREPARATIONS

(See N. N. R., 1919, p. 319)

ICHTHYOL.—Ammonium Ichthyol.—An aqueous solution the important medicinal constituents of which are ammonium compounds containing sulphur in the form of sulphonates, sulphones, and sulphides. These characteristic forms of sulphur result from the sulphonation of the tar-like distillate obtained from the bituminous shales, found near Seefeld in the Tyrol, and containing the fossil remains of fish.

Actions and Uses.—Ichthyol is weakly antiseptic and mildly irritant. It penetrates the skin to some extent and is said to cause some vasoconstriction on mucous membranes. Taken internally it produces some gastro-intestinal irritation, with diarrhea, etc. Its influence on metabolism has not been determined.

It is used locally under the supposition that it will secure the absorption of swellings and effusions in contusions, burns, etc., and especially in gynecologic practice, and in various skin diseases. Ichthyol has been tried internally in a great variety of conditions, but its therapeutic value in many of its suggested applications has not been fully established.

Dosage.—Internally, from 0.2 to 2 Cc. (to 30 minims) mostly in simple solutions in water, or peppermint water, sometimes in the form of pills or capsules. Locally, in vaginal, uterine or rectal suppositories, in from 0.06 to 0.18 Cc. (1 to 3 minims) bougies, or from 1 to 3 per cent. solution in treatment of gonorrhea. Ointments containing from 10 to 40 per cent. petrolatum may be prepared, using as a base fat, lanolin or petrolatum.

2. From Fantus, Bernard: Candy Medication, St. Louis, C. V. Mosby Company, 1915.

Manufactured by the Ichthylol Co., Hamburg, Germany (Merck & Co., New York). German patent No. 35,216. U. S. trademark No. 62,603.

Ichthylol is a reddish-brown to brown-black, syrupy liquid having a characteristic, empyreumatic odor and burning taste.

It should be completely soluble in water; incompletely soluble in alcohol or ether, but nearly soluble in a mixture of equal volumes of alcohol and ether; also soluble in a mixture of equal volumes of alcohol, water and ether. It is miscible with glycerine.

The aqueous solution of ichthylol (1:10) has a faintly acid reaction on blue litmus paper. The aqueous solution of ichthylol (1:10) yields a greenish-black, resin-like precipitate on the addition of hydrochloric acid. This precipitate is nearly insoluble in ether; it is partially soluble in alcohol; soluble in water, but if dissolved in the latter solvent it may again be precipitated from solution by the addition of hydrochloric acid. With barium chloride test solution the aqueous solution of ichthylol (1:10) gives a brownish-black precipitate which is insoluble in diluted hydrochloric acid. If the aqueous solution (1:10) be boiled with potassium hydroxide test solution ammonia should be evolved. If 1 Gm. of ichthylol be ignited it should leave no weighable residue. If 10 Gm. of ichthylol be diluted with 90 Cc. of water, the mixture placed in a glass-stoppered cylinder and allowed to remain undisturbed for twenty-four hours, no deposit should form.

If dried at 100 C. ichthylol should not lose more than 47.0 per cent. of its weight (absence of an undue amount of water). If from 5 to 6 Gm. of ichthylol be weighed into a flask, 25 Cc. of potassium hydroxide test solution and 100 Cc. of water be added, the mixture distilled until no more ammonia passes over, the distillate collected in 15 Cc. of normal sulphuric acid to which 1 drop of methyl orange test solution has been added, and the excess of acid then titrated with tenth-normal potassium hydroxide, the amount of normal sulphuric acid consumed should correspond to from 2.9 to 3.4 per cent. of total ammonia (NH₃). If from 5 to 6 Gm. of ichthylol be weighed into a beaker, diluted with 50 Cc. of water, 10 Cc. of a 10 per cent. solution of albumin added, followed by 5 portions of 5 Cc. each of diluted hydrochloric acid, shaking after each addition, the mixture made up to a volume of 500 Cc. and filtered through a dry filter, and if 200 Cc. of the filtrate be heated to boiling, 10 Cc. of barium chloride test solution added, the mixture allowed to stand for twenty-four hours, the precipitate of barium sulphate collected, heated and weighed in the usual way, the weight of barium sulphate obtained should correspond to from 5.7 to 6.2 per cent. of ammonium sulphate. If from 0.5 to 1 Gm. of ichthylol be weighed into a Kjeldahl flask, diluted with 30 Cc. of water, 5 Gm. of potassium chlorate added, followed by 30 Cc. of nitric acid, the mixture evaporated to about 5 Cc., 25 Cc. of hydrochloric acid added, this solution evaporated to about 5 Cc., 25 Cc. of hydrochloric acid again added, this solution evaporated to about 5 Cc., 100 Cc. of water added, this solution heated to boiling, 10 Cc. of barium chloride test solution added, the mixture allowed to stand for twenty-four hours, the precipitate of barium sulphate collected, heated and weighed in the usual way, the weight of barium sulphate should correspond to at least 10 per cent. of total sulphur. If the ammonia contained in the ammonium sulphate as previously determined in ichthylol be calculated, and the result subtracted from the "total ammonia" as previously determined, the remainder should represent the ammonia combined with the organic-sulphonic acids. If this value be multiplied by 1.88 the result should represent the sulphur present in the sulphonic acids in an oxidized state, i. e., the "sulphonic sulphur." If the sulphur contained in the ammonium sulphate as previously determined in ichthylol be calculated, and the result subtracted from the "total sulphur" as previously determined, the remainder should represent the sulphur present in the organic sulphonic acids contained in the substance. If the "sulphonic" sulphur in ichthylol as previously calculated be subtracted from the sulphur in the organic-sulphonic acids as previously calculated, the remainder should correspond to at least 5.5 per cent. of "organic" ("sulphid") sulphur.

Ichthylol is incompatible with acid and saline solution, fixed alkalies, their carbonates and iodides, alkaloidal salts and mercuric chloride.

MERCUROCHROME-220

Preliminary Report of the Council on Pharmacy and Chemistry

A report on the experimental and clinical status of this new germicide for use in the genito-urinary tract by Young, White and Swartz was published in THE JOURNAL of the American Medical Association, Nov. 15, 1919. This product is prepared and marketed by Hynson, Westcott and Dunning, Baltimore, Md., who request its acceptance for New and Nonofficial Remedies. The available evidence on Mercurochrome-220 is thus far limited to the article mentioned—obviously confirmation of the work there reported is necessary before more than a tentative acceptance can be accorded. However, Mercurochrome-220 is a definite and nonsecret compound. This, together with the evidence presented in the publication referred to, may be sufficient to warrant its use by physicians, provided, however, it is recognized that its therapeutic status is in the experimental stage. The Council has, therefore, deferred acceptance of this product for New and Nonofficial Remedies, and authorized publication of this preliminary report.

For the information of those who desire to use this compound, the following preliminary statement, based chiefly on the article by Young, White and Swartz, of its physical and chemical properties, pharmacologic actions and proposed therapeutic application is published.

W. A. PUCKNER, Secretary.

MERCUROCHROME-220.—Mercurochrome-220 is stated to be dibromo-oxymercury fluorescein.

The empirical formula is C₂₀H₁₁O₅Br₂Hg.

Mercurochrome-220 is described as occurring as a red powder, odorless, containing about 28 per cent. of mercury.

Mercurochrome-220 is insoluble in water, but soluble in alkalies, forming a deep cherry-red solution which fluoresces on dilution. The solution is stable in the air at ordinary temperatures, is not affected by moderate heating and does not respond to the usual tests for mercury ions. Alkaline solutions are incompatible with acids. The solution stains the skin red but the stain may be removed by rubbing first with 2 per cent. potassium permanganate solution and then with 2 per cent. oxalic solution. On ignition, Mercurochrome-220 leaves no ash.

Pharmacologic Action.—According to Young, White and Swartz, this compound is a strong and rapidly active germicide; it is active in urine, a 1:1,000 solution killing *B. coli* and *Staphylococcus aureus* in this medium in one minute. It penetrates the tissues readily. The drug is tolerated in a strength of 1 per cent. by the bladder, renal pelvis and urethra; a 2.5 per cent. solution applied to the anterior urethra caused only temporary discomfort. The toxicity, when tested by intravenous injections into rabbits, was found to be rather high, 10 Mgm. per kilo. invariably causing death within 24 hours and 5 Mgm. causing a decrease in phenolsulphonephthalein output and an albuminuria that lasted about a week. Dogs were more resistant. No systemic effects have been observed following its local application in the human.

Therapeutic Applications.—The drug has been used by Young, White and Swartz in infections of the renal pelvis, in cystitis and urethritis and in chancroidal ulcerations. In the treatment of infections of the kidney pelvis, the ureters were catheterized and the pelvis gently filled with a 1 per cent. solution of the drug; the catheter was plugged and the solution retained in the pelvis for five minutes. In the treatment of bladder conditions, one ounce of the 1 per cent. solution was introduced into the bladder and retained for one hour or longer, the treatment being given daily or on alternate days or at longer intervals according to circumstances. In anterior gonococcus urethritis, the anterior urethra was filled with a 1 per cent. solution and retained for five minutes; if the posterior urethra was involved, the solution was gently forced into the posterior urethra and bladder and retained for an hour or more.

Later, in the treatment of acute anterior gonorrhea, 2.5 per cent. solution¹ was used every three hours. In the case of chancroidal ulcerations, the drug was applied as a moist dressing (1 per cent.) or as a starch paste (5 per cent.) or as an ointment (5 per cent.).

The results have been satisfactory and no untoward effects observed. Cases of long-standing, purulent cystitis have cleared up in a few days; in the case of gonorrhea, the discharge became free of the organisms in from three to seven days, the average being ten. The chancroidal ulcerations cleared off in from one to four days.

BARBITAL SODIUM (See N. N. R., 1919, p. 83).

Veronal-Sodium—A brand of barbitol sodium complying with the N. N. R. standards.

Manufactured by the Winthrop Chemical Co., Inc., New York. U. S. patent No. 782,739. U. S. trademark No. 40,115.

PROCAINE (See New and Nonofficial Remedies, 1919, p. 30).

Procaine-Calco.—A brand of procaine complying with the N. N. R. standards.

Manufactured by the Calco Chemical Co., Bound Brook, N. J. U. S. Patent No. 812,554 (Feb. 13, 1906; expires 1923) by license of the U. S. Federal Trade Commission.

TYPHOID VACCINE (See New and Nonofficial Remedies, 1919, p. 292).

E. R. Squibb and Sons, New York.

Typhoid-Paratyphoid Bacterin (Special Bacterial Vaccine No. 13).—Marketed in 5 Cc. vials, each cubic centimeter containing 1,000 million killed *B. Typhosus*, 750 million killed *B. Paratyphosus* "A," and 750 million killed *B. Paratyphosus* "B."

1. In the article by Young, White and Swartz, J. A. M. A. 73: 1483, 1919, it was stated that a 25 per cent. solution was being used; this was an error, J. A. M. A. 73: 1708, 1919.

CAROTINEMIA

Abnormal pigmentation of the body, as well as the appearance of unusual pigments in the fluids and secretions of the organism, has always elicited the interest of physicians. In recent years a new appreciation of the significance of some of these manifestations has come through the recognition that certain ingested pigments, notably the so-called carotinoids, are easily incorporated into the tissues. Under the general designation of "lipochromes" they have been recognized as the coloring matters of milk fats and body fats, of egg yolk, of the corpus luteum, and of other structures. Recently the lipochrome of nerve cells has also been identified as carotinoid coloring matter—carotin and xanthophyll pigments—derived from the food.

Through numerous researches of Palmer and his associates¹ in this country, it has become known that different species vary in their tendency to carry carotinoids in the blood serum. Man represents one of those capable of such distribution of the pigments, frequently derived from plant sources, which tend to give a yellow color to body fats, analogous to that of butter and egg yolk. Not until quite recently has it been appreciated, however, that certain unusual colorations indicated by a yellowish complexion are referable to the food pigments. Under the designation of carotinemia, Hess and Myers² have recently described in THE JOURNAL what they regard as a new clinical picture. The yellow discoloration of the skin observed in their cases resembled a mild jaundice except for the noninvolvement of the sclera. Hence, as they suggest, this pigmentation has no doubt frequently been confused with mild grades of icterus or attributed to some obscure metabolic disturbance. Through the careful laboratory examinations made by Hess and Myers it is demonstrated that a diet rich in carotin, as it is furnished by carrots, spinach, egg yolk and oranges, may produce the manifestations. It is the merit of these American investigators to have demonstrated an

actual carotinemia, that is, tingeing of the blood plasma with pigment which was chemically identified as carotin. They point out that as carotin pigment is a constituent of much of our vegetable food, carotin discolorations are most likely to occur in those subsisting on diets rich in vegetables.

By a coincidence attributable to war-time dietary conditions, necessitating widespread liberal use of vegetable foods, what is evidently the same type of coloration has been widely observed in Europe during the past few years. Kaupe³ described the jaundice-like complexion of children in Bonn who had received considerable quantities of carrots as food. The pediatrician Stoeltzner⁴ at Halle, who has observed similar cases after the ingestion of carrots, designates the condition as "pseudo-icterus," and issues a warning against confusion with jaundice. The lack of sclerotic discoloration affords an easy differential diagnosis. Klose,⁵ who observed the same phenomenon in Silesia, has called attention to the peculiar hue or orange-yellow tint which serves to differentiate the discoloration due to carotin-bearing foods. He also points out that it is most commonly observed in the better nourished children. This can be understood if we recall that the carotin pigment is fat-soluble and hence tends to migrate more readily when an abundance of fat is available.

Moro⁶ evidently observed long ago the same type of discoloration in infants after the feeding of so-called carrot soup, and its cause was ascribed to carotin at that time. The phenomenon is by no means confined to the young or adolescent individual. The possibility of comparatively larger intakes of the responsible pigments in the diet may render the incidence of the discoloration more frequent in children; or it may be that the paler skin of the young renders the yellow complexion more readily detected and hence only apparently more common in childhood. Schüssler⁷ has described what is undoubtedly a carotinoid pigmentation in three men beyond middle life who had been obliged to subsist largely on carrots because of the shortage of potatoes where they lived. Furthermore, it was in adults that von Noorden and Salomon⁸ observed the comparable pigmentation termed by them "xanthosis" and most frequently seen in diabetics, presumably because the latter frequently subsist on vegetable (that is, carotin-containing) diets. Hymans, van den Bergh and Snapper,⁹ as well as Umber¹⁰ sus-

pected the identity of the "xanthosis" pigment with that of carrots. Spectroscopic examination seemed to verify this.

Hess and Myers,² whose investigations represent the latest word on this subject and thus serve to direct the attention of American clinicians to a phenomenon earlier noted in Europe, have noted that in cases of carotinemia the urine as well as the blood serum was colored yellow. When a small quantity of concentrated carotin was fed, the pigment reappeared rapidly in the urine. This significant fact, so far as we are aware, has never before been reported for man.¹¹ It will henceforth be necessary to deal with the possibility that some of the yellow urine pigment—the indefinite so-called urochrome—is of exogenous origin rather than the descendant of blood or bile pigments, as is now commonly taught.

METHYL-WOOD-ALCOHOL AND ITS END-PRODUCTS IN THE BODY

The menace of methyl alcohol or wood spirits to human health, though long known to physicians, has never been adequately appreciated by the public. Heretofore the dangers arising from its introduction into the body have for the most part been confined to some accidental or casual intake of the substance, and larger numbers of fatalities have arisen only in unusual circumstances, such as the criminal adulteration of alcoholic beverages with wood alcohol. With the enforcement of national prohibition, however, the prospect of more frequent instances of harm through the use of this intoxicant in place of the forbidden grain spirits and other drinks containing ordinary ethyl alcohol is unfortunately before the nation. Within the last few weeks the newspapers have reported the deaths of more than a hundred persons from the adulteration of alcoholic beverages with methyl alcohol. It therefore becomes more necessary than ever to understand the toxicology of methyl alcohol and its behavior in the body. To combat an enemy we must learn to know its mode of attack.

Chemically, the difference between methyl alcohol (CH_3OH) and ethyl alcohol ($\text{CH}_3\text{CH}_2\text{OH}$) is not striking, though the methods of preparation are dissimilar. When wood is subjected to destructive distillation, methyl alcohol is one of the products formed. Ethyl alcohol is derived from the fermentation of grains or fruits. Wood alcohol, about 10 per cent., may be added to ethyl alcohol to render the latter unfit for beverage purposes, and the government has ruled recently that such denatured alcohol must bear on the label a special warning concerning the dangers of methyl alcohol. Elsewhere in this issue appears the report of a case of wood alcohol poisoning thoroughly

studied with reference to the symptomatology and pathology.¹ When death occurs, there is usually coma, with death from respiratory paralysis. According to our present knowledge, methyl alcohol is eliminated slowly from the body, an end-product of the oxidation in the body being formic acid.

Formic acid, HCOOH , has been recognized as an excretory product of methyl alcohol since Pohl² demonstrated, in 1895, that introduction of this alcohol into the stomach leads to an increased output of formic acid in the urine. Hence the latter affords a possible means of ascertaining whether or not wood alcohol has been taken into the organism. A mere qualitative test for formic acid, however, will not suffice; for this substance has been known, at least since 1877,³ as a normal constituent of the urine. Therefore it is essential to know something regarding the extent to which formic acid may occur in the urine under what may be called normal conditions of living. According to Autenrieth,⁴ the quantity eliminated may vary considerably in different persons, though it tends to exhibit a uniformity in an individual living on a fairly uniform diet. The figures approximate 0.25 gm. a day as an illustrative average.

When methyl alcohol is ingested, the output of formic acid in the urine promptly increases. For example, a person who had taken 80 gm. of pure methyl alcohol in the course of eight days showed an extra elimination of formic acid above his usual output equivalent to 5 per cent. or more of the consumed spirits. It will be observed that even when these relatively innocuous doses were taken, a quantitative investigation betrayed the intake. With larger doses, methyl alcohol itself, which is missed in such instances as that just cited, may appear in the urine. Other alleged precursors of formic acid, such as glucose, and lactic acid which might readily be taken into the body in exceptionally large quantities in the course of an ordinary regimen, were found by Autenrieth to be without appreciable influence on the output. Formaldehyd, HCOH , did not produce an increment; but formic acid itself was quite resistant to oxidation in the body, so that unlike many other organic acids it again reappeared in the urine in considerable proportions unchanged. Fortified with these facts, the chemist will be better prepared to ascertain the occurrence of poisoning with wood alcohol when the direct evidence may be lacking or inconclusive. At the present juncture the public should be made to appreciate that methyl alcohol is a dangerous poison; that one of its serious effects is permanent blindness, and that it may be so prepared as to be ordinarily indistinguishable by

11. Kaupé (Footnote 3) specially records the absence of apparent changes in the urine in the cases observed by him.

odor or taste from ethyl alcohol. It should be emphasized that the selling or promoting the sale of or use of either methyl or ethyl alcohol as a beverage is the doing of an unlawful act.

DEATHS OF PHYSICIANS IN 1919

During 1919, the deaths of 2,105 physicians of the United States and Canada were noted in THE JOURNAL. Adding 2.5 per cent. to this number on account of delayed reports and possible omissions, we may estimate the total number of deaths to have been 2,163. As the total number of physicians classified in the American Medical Directory is 159,444, we may estimate that the annual death rate approximates 13.29 per thousand. The average annual mortality for the period from 1914 to 1919, inclusive, is approximately 14.81.

Ages.—The age at death varied from 24 to 100, with an average of 59 years, 1 month and 25 days. Of the decedents, 88 were under 30; 239 between 31 and 40; 280 between 41 and 50; 442 between 51 and 60; 498 between 61 and 70; 366 between 71 and 80; 156 between 81 and 90, and 18 between 91 and 100. The greatest mortality occurred at the age of 59, at which 62 deaths were recorded.

Years of Practice.—The number of years of practice varied from 1 to 76, the average being 32 years, 5 months and 26 days.

Causes of Death.—General diseases caused 250 deaths; diseases of the nervous system, 248; diseases of the circulatory system, 369; diseases of the respiratory system, 334; diseases of the digestive system, 114; diseases of the genito-urinary system and skin, 156; senility, 320; suicide, 38; accident, 103; homicide, 35, and 90 deaths occurred after surgical operations. Among the principal assigned causes of death were: pneumonia, including influenzal pneumonia, 313; organic heart disease, 222; cerebral hemorrhage, 203; nephritis, 121; malignant disease, 78; tuberculosis, 66; angina pectoris, 53; arteriosclerosis, 35; septicemia, 31; diabetes, 30; appendicitis, 27; myocarditis, 23; uremia, 17; anemia, 16; kidney disease (unclassified), 15; cirrhosis of the liver, and gastritis, each, 14; peritonitis, 12; acute dilatation of the heart, and endocarditis, each, 11; embolism and thrombosis, each, 10, and other diseases, less than 10.

Violence.—There were 176 deaths from violence. Of these, 103 were due to accident and were: automobile, 42; automobile-railway (grade crossing), 15; poison, 10; drowning, 7; street car accidents, falls and railway accidents, each 5; injuries by horses and vehicles, 3; asphyxia, gunshot wounds and other accidental traumatisms, each 2; aeroplane, injuries by animals, explosion, burns and crushing, each 1. The 38 physicians who ended their lives by suicide selected the following methods: firearms, 18; poison, 11; strangulation, 3; cutting instruments, and causes not stated, each, 2; asphyxia, 1, and jumping from high places, 1. Of the 35 homicides, 21 occurred as the result of wounds received in battle; 10 were due to firearms; 3 were unclassified, and one was due to strangulation.

Influenzal Pneumonia.—The graphic chart shows the deaths of physicians from pneumonia and influenzal pneumonia and from all causes for the years 1918 and 1919, and indicates clearly the exceedingly rapid increase that occurred during October, November and December, 1918.

Military Service.

—The deaths of 21 officers of the Army and Navy are reported to have occurred as the result of wounds received in battle; 37 officers died abroad from disease; 3, from accident; 2, from suicide, and one was murdered. During the year, 143 physicians died who had served in the Civil

Deaths from influenzal pneumonia and from all causes during 1918-1919: solid line, deaths from all causes; broken line, deaths from influenzal pneumonia.

War, and of these 33 had followed the fortunes of the Confederacy, 45 had been officers of the United States Volunteers, 17 were veterans of the war with Spain, and 5 had served in foreign wars. The Medical Corps of the Army, including the Medical Reserve Corps, lost 325 officers and 11 contract or acting assistant surgeons. The Navy lost 29 medical officers, the United States Public Health Service, 9; the United States Indian Service, 4, and the organized militia, 22, of whom 5 had attained the grade of Surgeon-General.

Civil Positions.—Of those who died, one had been a member of Congress; 22, members of the lower house of legislature; 29 had been mayors; 15 had been members of state boards of health; 12, members of state boards of medical examiners, and 2, members of other state boards.

Association Officers.—Among those who died, one had been President of the American Medical Association, three had been members of the House of Delegates, and two members of the Board of Trustees.

THE TEACHING OF CLINICAL MEDICINE

Teachers of technical subjects naturally fall into one of two groups: first, the type whose interests lie mainly in the philosophic aspects of the subject taught, and second, the type who think of problems in terms of the individual. As Addis¹ has recently pointed out, this is true of clinical medicine, and it is equally true of clinical surgery or of any other clinical subject. Some clinicians who are mainly interested in underlying principles may be described as the investigative type. Others who are chiefly interested in the problem of the individual patient may be regarded as the practical type.

Quite frequently it has been assumed, particularly by the general practitioner and by the man on the street, that the two types are antagonistic, and this assumption is not without some basis in fact. It is doubtless true that the person with the investigative type of mind dislikes to be torn from his laboratory to attend to the details of the wards. We can all recall John Hunter's famous remark under circumstances of this sort that he must "go out and earn that damned guinea." It is equally true that the so-called practical clinician finds it difficult to detach himself from the study of disease in the patient to study disease by laboratory investigation. To this extent there is antagonism between the two types of clinicians; but the assumption that the investigative type is necessarily a feeble-minded putterer when it comes to practical medicine is not correct. Nor is it correct to assume that the practical type of clinician is incapable of grasping the principles of research and of appreciating its importance.

As Addis points out, the teacher of clinical medicine at the present time is in difficulties because he is expected to combine in one person the attributes of these two types. He is expected to be a practical clinician capable of diagnosing and treating disease in the individual, and he is also required to demonstrate his ability to do laboratory research. True, there are those who possess the characteristics of both types, but they are exceptional. The details concerned in the study and treatment of disease have become more and more complicated as our theoretical knowledge has increased. New principles and new methods are constantly being discovered by the investigator, and new applications of these principles and methods to clinical work are continually being made. This has caused a great increase in the routine work involved in the study of a given case and has greatly complicated the task of the practical clinician. Indeed, as Addis points out, the complexity of modern diagnosis and of modern treatment is so great that all of the energies of one man may well be utilized in organizing and conducting this side of the work of a teaching hospital.

It is quite possible that, as has been suggested, we are approaching the time when there will be two types of persons connected with each clinical department, namely, the clinical physiologist, whose chief work will be the intensive study of selected groups of cases and the instruction of students in the application of the principles of physiology to the elucidation of disease, and the clinician, whose chief function will be the care of the patient and the instruction of the student in the practical methods of diagnosis and treatment. Obviously, some such arrangement already exists in some of our better schools. In institutions in which full time medicine has been introduced, there has been a distinct effort to appoint as heads of the clinical departments men of the investigative type. One question that Addis' discussion raises is whether in our enthusiasm for laboratory research we have not overlooked the importance of purely clinical investigation and of the type of physician that naturally tends toward this.

Current Comment

HORSE SERUM VS. DIPHTHERIA ANTITOXIN

Many physicians have been wondering what would be revealed when the veil was raised which has hidden Germany and Austria from the rest of the world during the war. Physicians have been scanning German literature as it began to filter in to see what the Germans have done in medical science. Thus far nothing has been revealed which might be regarded as epoch making. One episode is especially interesting and worthy of note. We are indebted to *Medical Science, Abstracts and Reviews* of London for the references referred to. The average physician believes that the use of diphtheria antitoxin in the treatment of diphtheria had long ago been accepted as a specific and satisfactory method. It has often been cited as typical of definite progress in therapeutics and as an example of what scientific medicine has accomplished. It was startling, therefore, to read that a German investigator, Bingel,¹ perhaps carried away by recent work with nonspecific proteins had come to the conclusion that ordinary horse serum was just as effective as antidiphtheritic serum. He reports his conclusions in 471 cases of diphtheria treated with antitoxin, comparing them with 466 cases treated with ordinary horse serum; he claims to have found no difference in the results; in fact, that the results with ordinary horse serum in some instances were better. He concluded finally that the success of serum therapy in diphtheria could not be attributed to the antitoxin content of the serum and suggested that the large doses used, containing thereby large quantities of horse serum, were responsible for the good results. As might have been expected, Bingel's results and conclusions were not accepted. Numerous articles

1. Bingel, A.: Ueber Behandlung der Diphtherie mit gewöhnlichem Pferdeserum (Vergleich zwischen 471 mit antitoxischem Diphtherieheilserum und 466 mit gewöhnlichem Pferdeserum behandelten Diphtheriefällen—kein Unterschied), *Deutsch. Arch. f. klin. Med.* 125: 284-332, 1918.

1. Addis: *Edinburgh M. J.*, N. S. 23: 235, 1919.

appeared invalidating the conclusions. Feer,² working in the Zurich University Children's Clinic, at once compared sixty-five cases of diphtheria treated with antitoxin with fifty-seven treated with ordinary serum, giving the ordinary serum only in mild cases. He found that the cases treated with ordinary serum, although mild and not ill for so long a time as the others, required five to seven days for the throat to become clean, as compared with three days for those treated by antitoxin. In six cases it was necessary to inject diphtheria antitoxin subsequently in order to obtain a satisfactory result. Moreover, he observed that the membrane again appeared in from three to nine days after the injection of ordinary serum. His results were so definitely in favor of antitoxin that the experiment was not continued. Feer was unable to understand Bingel's results and even suggests that they may have been due to his having used serum from horses which had previously supplied antitoxin. In the same way other German clinicians and experimenters, including Joannovics,³ Friedberger⁴ and Kolle,⁵ confirmed the prophylactic and curative value of diphtheria antitoxin and demonstrated the inefficacy of ordinary horse serum in experimental diphtheria.

THE PROTEIN SHOCK REACTION

When vaccine therapy came into vogue many years ago, one of the points on which the earlier writers laid emphasis was the specificity of the reaction. As time has gone on, more and more doubt has been expressed regarding this specificity. It has been shown experimentally that a variety of substances of a protein nature are capable, when introduced into the body, of causing a reaction on the part of the body cells and fluids with the stimulation of the immunity-producing mechanism. Practical advantage of these studies in the treatment of disease was first sought in this country. Among the earlier studies were those of Miller and Lusk, of Cecil, and of Gay, which indicated the possible value of this form of treatment. In typhoid fever to some extent, but particularly in the treatment of various forms of arthritis, the administration of protein has proved of value. Such administration leads to a reaction that is now spoken of as the protein shock reaction, and this reaction is indeed the greatest drawback to the treatment. Patients capable of reacting to the treatment usually have a severe chill with fever and very often headache and general pains, which may be accompanied by nausea and vomiting and may last for several hours. This is accompanied by a primary fall and a secondary rise in the leukocytes, which may be taken as an indication that the tissues are reacting. Recently Gow⁶ has substantiated previous studies regarding the reaction on the part of the

leukocytes and the general reaction on the part of the patient. While the method is not one that has as yet been widely used, it seems to merit more extensive, careful study.

SIR WILLIAM OSLER

Osler is dead. These three words announce the passing of a man most influential for all that was good; noted for his kindly spirit, well beloved as a teacher and physician. The life of Sir William Osler, more than his works, placed him at the pinnacle of his profession. His winning personality, his cheerful disposition, his faith in mankind, but above all his love for his profession made him what he was—the great physician. Added to these is the fact that from boyhood to his last illness he was a tireless student, an enthusiastic, unceasing worker. His contributions to medical literature, recently compiled, include 730 titles; elegance of style, conciseness of statement and literary quality of his manuscripts marked him as a careful, conscientious writer. His contributions, whether as textbook, periodical literature or spoken word, were examples of masterly English diction. During his long career Sir William Osler was the recipient of practically every honor which the medical profession could bestow on those of merit in its ranks, culminating last July in the international celebration of his seventieth birthday. The occasion was marked by the felicitations and congratulations of the medical world. A memorial volume was prepared containing essays by students and colleagues and presented to him by a distinguished committee. In response to the presentation address Dr. Osler said:

"To have had the benediction of friendship follow one like a shadow, to have always had the sense of comradeship in work, without the petty pinpricks of jealousies and controversies, to be able to rehearse in the sessions of sweet, silent thought the experiences of long years without a single bitter memory, fill the heart with gratitude. That three transplantations have been borne successfully is a witness to the brotherly care with which you have tended me. Loving our profession, and believing ardently in its future, I have been content to live in it and for it. A moving ambition to become a good teacher and a sound clinician was fostered by opportunities of an exceptional character, and any success I may have attained must be attributed in large part to the unceasing kindness of colleagues and to a long series of devoted pupils whose success in life is my special pride."

The statement quoted is characteristic of the man. It shows why he was loved, why he succeeded—why his name will appear in the history of medicine as an example of the ideal physician.

Cuba's Fine Smallpox Record.—Our exchange *Vida Nueva* of Havana cites the recent smallpox death rate in various countries from 70 in France, 78 in England and 1,057 in Portugal to Spain's 1,262, while Cuba was the only country on the direct paths of commerce which had no cases. Havana had 1,654 cases in 1887; 1,404 in 1897; 2 in 1900, and then for ten years not a single case. As was mentioned recently, there has been a small epidemic in Cuba, for the first time in seventeen years, notwithstanding the opportunities for importation of the disease.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Convicted of Misuse of Mails.—Dr. George F. Purcell of Los Angeles was found guilty of misusing the mails to give information where an illegal operation might be performed. The case is the first of a series of six brought by the government for similar offenses.

Illegal Practitioners Arrested.—Drs. Harry G. Palmer and Jay G. McMath, osteopaths of Compton, according to report, have been arrested on a charge that they murdered Mrs. Marie Vegas Martinez, who died as the result of an alleged illegal operation performed by them. The report states also that T. Wah Hing, a Chinese herb doctor, who has been practicing in Sacramento for many years, was convicted of practicing medicine without a state license.

Personal.—Dr. John A. Reily, medical superintendent of the State Hospital, Patton, has been reelected executive head of the institution.—Dr. Ethel M. Watters, San Francisco, has been appointed head of the new bureau of child hygiene.—Dr. Ray W. Karras has been reappointed surgeon to the Soldiers' Home, Los Angeles.—Robert M. Dodsworth, Major, M. C., U. S. Army, Long Beach, was honor guest at the meeting of the Harbor Medical Association, November 28.

Popular Medical Lectures.—Stanford University Medical School announces the thirty-eighth course of popular medical lectures, to be given at Lane Hall, San Francisco, on alternate Friday evenings at 8 o'clock.

Jan. 9, 1920: "The Cause and Prevention of Nervousness," by Dr. Julian Mast Wolfsohn, San Francisco; Jan. 23: "The Philosophy, Cause and Prevention of Disease," by Dr. Walter V. Brem, Los Angeles; Feb. 6: "The Hospital and the Public," by Dr. William Raymond Dorr, San Francisco; Feb. 20: "The Out-patient Clinic as a Health Center," by Dr. Alfred Cummings Reed, San Francisco; March 5: "The Problem of the Drug Addict," by Dr. Robert Eugene Bering, San Francisco, and March 19: "The Health Age," by Mr. Celestine Sullivan.

ILLINOIS

Personal.—Dr. Boleslaus Klarkowski, member of the Chicago Board of Education, sustained serious burns of the eye by explosion of chemicals, December 22.—Dr. John A. Wheeler, Springfield, formerly sheriff of Sangamon County, has been appointed medical director of the juvenile court.

Illegal Practitioner Again Fined.—J. P. Vizgird, St. Louis, has again been fined \$200 and costs by the Department of Registration and Education for practicing medicine in Illinois without a license. The case had been pending against Vizgird in the St. Clair (Ill.) County Court for several months. Following the formal disposition of this case, five more informations were filed against Vizgird for violating the Medical Practice Act and he was compelled to give bond before he was permitted to return to St. Louis. Vizgird paid his fine and promised never to practice medicine in Illinois again so the remaining charges were dismissed. He had been fined for a similar offense in June, 1918.

Venereal Diseases in Illinois.—The division of social hygiene, state department of public health, has recently issued a report of known cases of venereal diseases in Illinois for the year ending June 30, 1919. The total number of cases reported is 11,915 with about 5,000 additional cases treated in the several clinics conducted by the state. There were 7,756 cases reported among males with 502 cases of syphilis, 5,752 cases of gonorrhea and 474 cases of chancroid. Total number of women infected was 4,159 of whom 1,808 were victims of syphilis, 2,342 were suffering from gonorrhea and nine from chancroid. Six hundred and fifty-six of these victims of venereal disease were employed in the handling of foodstuffs.

Chicago

The Quine Dinner.—A dinner was given to Dr. William E. Quine, December 27, in celebration of his completion of half a century in the practice of medicine. More than 300 of Dr. Quine's friends were present to do him honor. Dr. Frank Billings was toastmaster; Dr. David Kinley, dean of the University of Illinois, Urbana, spoke on "The Doctor and

the Community"; Dr. Daniel A. K. Steele, on Dr. Quine as "The Colleague"; Mr. John T. Richards, on Dr. Quine as "The Man," and Dr. James B. Herrick, on Dr. Quine as "The Physician." Dr. William A. Pusey presented Dr. Quine with a book containing the autographs of those present at the dinner.

INDIANA

Personal.—Dr. Varney Hazlewood, Bedford, has been appointed head physician of the Indiana State Sanatorium, Rockville.

Smallpox at Evansville.—The Evansville Board of Health reported, December 4, that there were eighty cases of smallpox in the city, three fourths of the number being children.

Judgment Awarded Physician.—Dr. William F. Walsh, Indianapolis, was awarded a judgment of \$4,000 against Patrick, Edward and Dennis Bryan, whom he charged with malicious prosecution.

Parking Privileges Extended.—Mayor Jewett of Indianapolis has signed an amendment to the traffic ordinance, extending to three hours the limit for parking in the congested districts for physicians who have downtown offices.

Illegal Practice Charged.—The State Board of Medical Registration and Examination filed affidavits, December 5, against B. C. Hendricks, a chiropractor of Kendallville, and A. J. Newman, Gary, who are alleged to be practicing medicine without a state license.

Society Reorganized.—Marshall County Medical Society has been reorganized and the following officers have been elected: president, Dr. Frank H. Kelly, Argos; vice president, Dr. Howard P. Preston, Plymouth, and secretary-treasurer, Dr. Harry Knott, Plymouth.

Anderson Clinic Organized.—The Anderson Clinic has been incorporated by Drs. Lee F. Hunt, Thomas M. Jones, Albert W. Collins, Weir M. Miley, George A. Whitledge, Henry W. Gante, S. G. McDonald, and Earl E. Brock. The clinic will be housed in a two-story brick building at Jackson and Twelfth streets, and will have clinical and pathologic laboratories, roentgen ray and all other necessary equipment. The clinic is incorporated for \$75,000.

Osteopath Sues Physicians.—A suit for \$50,000 damages for an alleged conspiracy to prevent him from practicing surgery in any of the hospitals of Fort Wayne, has been instituted by Kent L. Seaman, an osteopath, against Drs. Henry O. Bruggerman, Miles F. Porter, Ralph M. Bolman, Ben P. Weaver, Lyman T. Rawles, Edgar N. Mendenhall, John E. McArdle, L. Parker Drayer, Albert E. Bulson, Maurice I. Rosenthal, Homer E. Glock, all of Fort Wayne, and the Poor Handmaids of Jesus Christ, a corporation. An injunction is brought against all the defendants to restrain them from hindering him from the practice of surgery in St. Joseph's Hospital or elsewhere.

IOWA

Tuberculosis Hospital for Polk County.—Announcement is made that Polk County will have a \$100,000 tuberculosis hospital as soon as a suitable location is found.

Inebriate Hospital Closed.—The State Inebriate Hospital, Knoxville, was closed, December 1, on account of lack of patronage. At the time of closure only eleven patients were under treatment.

Personal.—David S. Fairchild, Jr., Col., M. C., U. S. Army, Clinton, chief surgeon of the Forty-Second Division, has been honorably discharged from the United States service.—Dr. Williams Cammack and Libby Seymour Cammack, formerly of Fort Dodge, have returned after twelve years' service as medical missionaries in Angola, Portuguese West Africa.

Laboratory Opened.—The Physicians' Club of Keokuk celebrated the formal opening of the Keokuk Clinical and Pathological Laboratory, December 2. The laboratory is operated by the state board of health, and Dr. Sarah R. Kellman is director. The physicians of the surrounding country were invited to a banquet which was followed by addresses by Dr. Henry Albert, Iowa City, who spoke on the laboratory from the standpoint of the laboratory man, and Dr. William H. Rendelman, Davenport, who discussed the value of the laboratory from the standpoint of the clinician.

Hospital Items.—St. Luke's Hospital, Davenport, was opened, October 15.—The United Lutheran Church Hospital has purchased the old Oaks Hotel, Clear Lake, and

will remodel the building for a hospital at an estimated cost of \$300,000.—Cedar Valley Hospital, Charles City, has resumed operation.—Sisters Hospital, at Grinnell, has been turned over by the contractors, and will soon be opened formally.—The Eleanor Moore Hospital, Boone, has been taken over by Boone County.—The cornerstone of the new main building of St. Thomas Emergency Hospital, Marshalltown, was laid recently with impressive ceremonies.

MASSACHUSETTS

King Thanks Harvard Unit.—King George V of England, in a communication received by Harvard University, expresses his personal appreciation of the service contributed by the Harvard Unit during its three years and a half of duty with the British Forces in France.

Floating Hospital Opens Shore Work.—The new on-shore department of the Boston Floating Hospital, which will care for babies during the winter, and specialize in research study, has been opened at 40 Wigglesworth Street, Boston, where three three-story houses rented from Harvard University have been renovated at a cost of about \$40,000.

Personal.—Dr. Ernest William Goodpasture, Boston, has been appointed assistant professor of pathology in Harvard University Medical School.—Dr. John H. Wyman, Medway, has been appointed associate medical examiner (coroner) for the Norfolk District.—Dr. Isidor D. Bronfin, superintendent and medical director of the Beth Israel Hospital, Roxbury, Boston, has resigned.—Dr. Robert B. Scales, Dorchester, Boston, has been commissioned lieutenant-colonel, M. R. C., U. S. Army.—Dr. Edward H. Bradford, Boston, has been reappointed president of the Massachusetts Hospital School.—Dr. Ernest B. Emerson, superintendent of the Brockton Hospital, has resigned and has returned to his former post as superintendent of the Rutland State Sanatorium.—Dr. Henry P. Walcott, chairman of the metropolitan water and sewerage board, Boston, has been retired after more than forty years in the service of the commonwealth of Massachusetts.—Dr. Thomas F. Joyce has been appointed superintendent of the Lawrence Municipal Hospital.

MICHIGAN

Club Election.—Charlotte Medical Club has elected Dr. Vinton J. Rickerd, president, Dr. Flavius J. Knight, vice president, and Dr. Stanley A. Stealy secretary-treasurer.

Fritch Sentenced.—A jury in Detroit is reported to have found Dr. George A. Fritch guilty of manslaughter, and he was sentenced, October 28, to serve from one to fifteen years in the state branch prison, Marquette, and was taken there to begin his sentence December 9.

Fires in Hospitals.—Fire destroyed Mercy Hospital, Big Rapids, December 1, with the loss estimated at \$100,000. Forty patients were removed, and it is reported that one individual lost his life.—Reid City Hospital burned, November 18, with a loss of \$5,000. The patients were removed without casualty.

Personal.—Dr. Griffith A. Thomas, Detroit, who resigned as police surgeon to enter the army in 1917, has returned to Detroit and resumed his work at police headquarters.—Dr. Eugene Miller, health officer of Battle Creek, has been elected director of the Michigan State Health Association.—Dr. Alvin H. Rockwell, Kalamazoo, has been elected president of the Michigan State Health Association.

Clinics for Practitioners.—The staff of the University Hospital, Ann Arbor, announces a series of medical, surgical and special clinics to be given on the afternoon and evening of the second Wednesday of every month and the morning of the following day. These clinics are intended to help practitioners to keep abreast of new and interesting developments. Difficult cases will be demonstrated and discussed. An added feature will be a clinicopathologic conference on cases coming to necropsy. The plan has been arranged to enable practitioners to see the maximum amount of clinical material with the least expenditure of time, and to carry out the policy of the hospital to put its teaching facilities at the service of the profession. Conferences will be held in the surgical amphitheater of the University Hospital unless otherwise stated. The schedule has been arranged with the view of allowing practitioners to make the best train connections in reaching and leaving Ann Arbor. The exercises will start at 1:30 p. m., 7:30 p. m. and 8:30 a. m. The first conference will be held, Jan. 14 and 15, 1920.

NEW JERSEY

Personal.—Dr. Wilfred M. Post, Princeton, has returned from Asia Minor, where he served with the Near Egypt Relief.—Dr. John Cook, Bayonne, has been appointed a member of the staff of the Dyersburg (Tenn.) General Hospital.

Banquet to Service Men.—Mercer County Medical Society gave a banquet, November 12, at Trenton, to thirty-one physicians of Mercer County who were in the United States service during the world war. Dr. Irvine F. P. Turner, Toronto, president of the society, officiated as toastmaster.

New Officers.—The nineteenth annual meeting of the Tri-County Medical Association of Morris, Sussex and Warren was held at Hackettstown, October 14, and the following officers were elected: president, Dr. Frederick P. Wilbur, Franklin; vice presidents, Drs. Henry W. Kice, Wharton, and Louis C. Osmun, Hackettstown; secretary, Dr. Charles B. Smith, Washington, and treasurer, Dr. Frederick W. Flagg, Rockaway.

Infant Mortality Rate.—During the first nine months of 1919, the infant mortality rate for Newark was 80.6 per thousand, as against 87.8 for the same period in 1918. This is held to be a very low rate, among the lowest in the country, and is especially noteworthy because Newark presents all the conditions that are held to make difficult a very low infant mortality rate, such as congestion, industrial community, milk supply coming from great distances, large foreign population, and a large percentage of births attended by midwives.

Mental Hygiene.—A new work has been introduced in the Bureau of Mental Hygiene, Mental Hygiene Social Service. A psychiatric social worker has been appointed to carry on the work. The objects are to aid the promotion of mental hygiene; to give assistance to the mentally maladjusted; to maintain psychiatric clinics, and to inform the public as to the cause and means of prevention of mental diseases and deficiencies. In the first month of its existence, forty-two cases were referred to this bureau by various organizations, charities and private individuals.

NEW YORK

Tuberculosis Survey.—The recent survey of Schenectady County shows that of 120 individuals examined, 17, or 14 per cent., were found positive, and 35, or 29 per cent., suspicious.

Laboratory for Montgomery County.—At a recent meeting of the board of supervisors of Montgomery County, it was voted to appropriate \$5,000 for the establishment of a county laboratory at Amsterdam.

Water Purification for Tonawanda.—The town of Tonawanda has voted to issue \$200,000 in bonds for a water purification works. The town has just recovered from an epidemic of typhoid fever, which was demonstrated to have been water borne.

Personal.—Dr. Thomas B. Carpenter, Buffalo, for many years first assistant bacteriologist of the laboratories of the department of health of Buffalo, has been appointed director of laboratories, succeeding Dr. William G. Bissell, deceased.—Dr. Grace M. Norris, Utica, has been elected coroner of Oneida County.

Want Reformatory Reopened.—An appeal has been made to John D. Rockefeller, Jr., to reopen the buildings which he established at a cost of \$500,000 near the Bedford Reformatory for Women, as a psychopathic hospital and institute for the study of social and mental hygiene, in connection with the work of the Bedford Reformatory. At the time Mr. Rockefeller erected the buildings he gave the state the privilege of buying them, but, as no action was taken, the buildings were closed.

New Officers.—The Albany County Medical Association, December 12: president, Dr. James N. Vander Veer; vice president, Dr. George W. Papen, Jr., secretary, Dr. Percival W. Harrig, and treasurer, Dr. Nelson K. Fromm, all of Albany.—Rensselaer County Medical Society, in Troy, December 9: president, Dr. Christopher J. Patterson (reelected); vice president, Dr. William J. Fleming; secretary, Dr. William Kirk, Jr., and treasurer, Dr. Russell F. Benson, all of Troy.—Onondaga County Medical Society at Syracuse, December 9: president, Dr. Harry J. Brayton; vice president, Dr. Robert Burns; secretary, Dr. George S. Reed, and treasurer, Dr. George M. Retan, all of Syracuse.

Clinics Combined.—The State Hospital Commission, which for some years, has been conducting clinics successfully

throughout the state in order to provide communities with facilities for the examination of cases of nervous and mental disorder, and the commission for mental defectives have evolved a program for a system of state-wide clinics. It is believed that better service can be rendered by combining the clinics for mental defectives with those for nervous and mental diseases. The first of these combined clinics was opened recently at Watertown, through the cooperation of Dr. William C. Sandy, New York City, and Dr. Paul G. Taddiken, Ogdensburg. It has been further suggested that these clinics could well be coordinated with the proposed system of health centers which the department of health desired to establish throughout the state.

Aid for Industrial Cripples.—The committee on education of the state reconstruction commission recently held a conference for the purpose of discussing plans for dealing with the problem of industrial cripples. According to statistics obtained by the commission, industrial casualties in the United States every year equal or exceed in number the country's total of wounded during the war. The questions particularly discussed were whether special schools and employment bureaus for industrial cripples were to be started and whether retraining and reeducation should be made compulsory. It was decided to urge the state immediately to inaugurate a policy of caring for men and women who are crippled through industrial accident or otherwise. A committee was appointed to draft proposals for the consideration of the legislature and to map out a program of rehabilitation. This is to be carried through irrespective of the federal bill now pending, in which \$1,000,000 is appropriated for the work, to be matched dollar for dollar by the several states.

New York City

Personal.—Dr. Abraham Strachstein has been appointed an instructor in urology in Columbia University.

Harvey Society Lectures.—The fifth lecture of the Harvey Society series will be delivered by Dr. Homer F. Swift, New York City, of the Rockefeller Institute, at the New York Academy of Medicine, January 10, on "Trench Fever."

New Hospital for Jamaica.—The trustees of the Jamaica Hospital, Queens, have planned to erect a new hospital building at a cost of \$250,000 on a plot of ground 200 feet square extending along Ridgewood and Lester avenues, Jamaica.

Fund for Visiting Nurses.—The Brooklyn Visiting Nurses' Association has adopted resolutions authorizing the raising of \$250,000 for work in that borough. A fund of \$25,000 to endow a visiting nurse in memory of Miss Elizabeth Hedin, who died during the influenza epidemic as a result of her devotion to cases under her care, will be a part of the campaign.

Division of Lectures Established.—The bureau of public health education of the department of health has instituted a division of lectures which is prepared to fill requests for lectures on any health subject, and especially on venereal disease. Societies or organizations desiring lectures may secure an appointment by communicating with Christine Kefauver, supervisor of lectures, bureau of public health education, 505 Pearl Street, Manhattan.

Health Department Sells Milk.—The health department has begun the sale of Grade B milk at 15 cents a quart at nine of its baby health stations. If the scheme is successful it will be extended to the entire sixty milk stations conducted by the health department. This is the grade of milk ordinarily retailing at 17 and 18 cents a quart. In this way Dr. Royal S. Copeland is endeavoring to develop a healthy competition which will eventually result in lower prices of milk delivered to consumers.

Cardiac Classes for Schoolchildren.—The cardiac class, conducted for the past two years by the Educational Alliance at East Broadway and Jefferson Street, has been so successful that three others have been started in Manhattan and one in Brooklyn. The results have been so gratifying that an appeal has been made to the board of education to provide special classes for children suffering from cardiac conditions. Beth Israel Hospital has been assisting at these cardiac classes with its social service department.

New Officers.—At the ninety-ninth annual meeting of the Medical Society of Kings County, December 16, Dr. John A. Lee was elected president; Dr. Arthur H. Bogart, vice president; Dr. Charles E. Schofield, secretary (reelected), and Dr. Robert L. Moorhead, treasurer, all of Brooklyn. At the annual meeting of the Queens-Nassau County Medical

Society at Jamaica, L. I., December 9, the following officers were elected: president, Dr. Arthur D. Jaques, Lynbrook; vice president, Dr. Thomas C. Chalmers, Forest Hills, and secretary-treasurer, Dr. James S. Cooley, Mineola.

OHIO

Personal.—Dr. Willard J. Stone, formerly of Toledo, has moved to Pasadena, Calif.

New Academy Officers.—At the annual meeting of the Dayton Academy of Medicine, December 12, Dr. Lynn M. Jones was elected president; Dr. Matthew Porter, vice president, and Dr. Edmund E. Bohlender, treasurer.

Academy to Issue Journal.—A new monthly medical journal to be called the *Academy Journal* is to be issued by the Cincinnati Academy of Medicine. Dr. Charles L. Bonifield is chairman of the committee to carry out this project.

Officers Elected.—The following officers of the Cleveland Medical Library Association were elected to serve during 1920: president, Dr. John P. Sawyer; vice president, Dr. Arnold Peskind; secretary, Dr. George E. Follansbee; treasurer, Dr. Clyde L. Cummer, and directing librarian, Dr. Carl A. Hamann.

Prizes to Nurses.—At the last meeting of the Medical Board of the Jewish Hospital, Cincinnati, it was announced that an anonymous donor had arranged to give prizes of \$60 each to the two highest ranking nurses in the first and second years of the training school, and prizes of \$120 each to the two highest ranking nurses among the graduating nurses of the institution.

Clinic Opened.—The Canton City Clinic was formally presented to the city by the Canton Chapter of the American Red Cross, December 11, and was accepted for the Canton Medical Society and the people of Canton by Dr. Austin C. Brant. The clinic is intended to be a stepping stone for a public or free city hospital. Dr. Harry P. Pomerene has been elected president, Dr. Charles A. Crane vice president, and Dr. Loyal E. Leavenworth secretary, all of Canton.

Prizes Awarded.—The Cleveland Medical Library Association awarded as prizes, to Cleveland physicians, the income from a fund established by Dr. Hamilton Fisk Biggar as follows: \$250 to Dr. Roy Gentry Pearce, for an essay on "Cardiorespiratory Mechanism in Health and Disease"; \$250 to Dr. Roy Wesley Scott, for an essay on "Studies of Pulmonary Emphysema," and \$100 to Dr. Marvin Da C. Shie for an essay on "The Importance and Scope of Modern Industrial Medicine."

PENNSYLVANIA

Increased Space for Sanatorium.—Dr. Edward Martin, Philadelphia, state commissioner of health, purchased, December 9, for \$20,000, the White Pine Inn and other property adjacent to the Mont Alto Sanatorium.

New Contagious Disease Hospital.—Bower Hill, near Woodville, Allegheny County, has been tentatively decided on as the site for a proposed new contagious disease hospital, to be erected under the direction of the county commissioners. A plan has been presented providing for a ninety-six room institution to cost about \$240,000.

Personal.—Dr. Stephen E. Tracy has been elected medical director of the Stetson Hospital, Philadelphia, succeeding Dr. Lewis S. Somers, resigned. Dr. Robert B. Mackey, Clark's Summit, has been commissioned major, M. C., Pennsylvania National Guard, and assigned to duty with the Thirtieth Infantry. Dr. John Murphy, Loretto, was given a testimonial, December 24, by the people of Loretto, in recognition of his services to the community for nearly forty years, and especially during the influenza epidemic of last year. Dr. Charles C. Cooner, Kulpmont, has been appointed deputy coroner of Northumberland County.

WASHINGTON

Personal.—Joseph A. McKee, Lieut.-Col., M. C., U. S. Army, has returned to Seattle, after an absence of three and one-half years, abroad. Dr. Frank P. C. Davis has been appointed city health officer of Kelso, succeeding Dr. Jeremiah Ballard.

New Hospital Building Plan.—The announcement is made that the Sisters of St. Joseph of Peace who have conducted the Wenatchee General Hospital for the last three years will immediately commence the erection of a \$75,000 hospital on a 3-acre site at the edge of the town.

WEST VIRGINIA

Clinical Conference.—The Ohio Valley General Hospital, Wheeling, announces that its attending staff holds clinical conferences twice a month, at the hospital, at which other physicians are invited to be present.

Staff Named.—Dr. Hugh H. Carr, Fairmont, has been named chief of the surgical staff of the Cook Hospital, and Dr. Edward W. F. Howard, Fairmont, chief of the medical staff of the institution, by the Marion County Medical Society.

Society Meetings.—The Eastern Panhandle Medical Society met at Charleston, December 10, and elected Dr. H. G. Tomkin, Berkeley County, president, Dr. Briscoe B. Ranson, Harper's Ferry, vice president, and Dr. Joseph M. Miller, Charles Town, censor. The next meeting will be held at Martinsburg. —Harrison County Medical Society at its annual meeting in Clarksburg, December 4, elected Dr. Solomon L. Cherry, Clarksburg, president, Dr. Arthur T. Post vice president, Dr. Irving D. Cole secretary, and Dr. Jesse F. Williams, treasurer.

WISCONSIN

Dispensary Opened.—The new Milwaukee Dispensary, on the third floor of the Saxe Building, has been opened under the charge of Dr. A. Harry Cohn.

Radium Association Incorporated.—The Physician's Radium Association has been incorporated at Milwaukee, with a capital stock of \$20,000, by fourteen physicians of Milwaukee.

Hospital Items.—A movement was recently started which promises to provide a modernly equipped hospital for Ripon. —Announcement has been made that the erection of a \$60,000 hospital at Stanley has been definitely planned.

Personal.—Dr. Francis W. Starr, Stanley, is said to have been fined \$25 for having broken the rule of the state board of health regarding public funerals over remains of persons having contagious diseases. —Dr. Augustus L. Beier, Chippewa Falls, has been appointed to succeed Dr. Alfred W. Wilmarth as superintendent of the State Home for Feeble-minded, Chippewa Falls.

New Officers.—At the annual meeting of the Milwaukee County Medical Society, December 11, Dr. Frank C. Studley was elected president; Dr. Clarence A. Baer vice president; Dr. Daniel Hopkins, secretary, and Dr. Arthur R. F. Grob, treasurer. —Waukesha County Medical Society at its annual meeting held in Waukesha, December 4, elected Dr. Floyd W. Aplin, Waukesha, president; Dr. George H. Perrin, Menomonee Falls, vice president, and Dr. S. Breck Ackley, Oconomowoc, secretary-treasurer. —At the sixteenth annual meeting of the West Wisconsin District Medical Society held in Eau Claire, November 23, Dr. Johan B. Mathiesen, Eau Claire, was elected president, and Dr. Herman F. Derge, Eau Claire, secretary.

CANADA

New President of McGill.—Sir Auckland C. Geddes, M. P., Montreal, who served during the war as Minister of National Service and Reconstruction, and president of the Local Government Board, formerly professor of anatomy at the Royal College of Surgeons, Ireland, and later professor of anatomy in McGill University, has been elected principal of the latter institution.

GENERAL

Tristate Physicians to Meet.—The annual meeting of the Tristate Medical Society of Virginia and the Carolinas will be held in Charlotte, N. C., February 18, under the presidency of Dr. Robert C. Bryan, Richmond, Va.

More Gifts by Rockefeller.—Of the \$100,000,000 Christmas gift of John D. Rockefeller, one half was given to the Rockefeller Foundation, and of this sum, \$5,000,000 is to be expended to the development and improvement of the leading medical schools in Canada, these schools being required to raise additional sums from other sources.

Congress on Internal Medicine.—The American Congress on Internal Medicine will meet in conjunction with the American College of Physicians in Chicago, February 23 to 28. The sessions will include daily clinics and laboratory demonstrations in hospitals and teaching institutions, and evening meetings, one of which will embrace the fourth annual convention of the American Congress of Internal Medicine.

Deaths from Wood Alcohol.—As a result of the use of substitutes for liquor containing methyl alcohol since prohibition became effective, 255 deaths have been reported in the United States, and of these about 140 followed Christmas celebrations. Of these deaths thirteen have thus far been reported in Chicago alone, and in New York there are said to be at least 100 cases of blindness following the use of wood alcohol.

Tristate Physicians Meet.—The Tristate Medical Society of Louisiana, Arkansas and Texas held its fifteenth annual meeting at Marshall, Texas, under the presidency of Dr. Edwin L. Beck, Texarkana, and elected the following officers: president, Dr. Charles R. Hargrove, Marshall; vice presidents, Drs. Lucian H. Lanier, Texarkana, Texas, Henry W. Jarrell, Mansfield, La., and Joe Becton, Greenville, Texas, and secretary, Dr. Frank H. Walke, Shreveport, La.

Ship Named for Red Cross.—The *Amcross*, a cargo vessel of 9,000 deadweight tons, was launched in the yards of the Merchant Ship Building Company, Chester, Pa. *Amcross*, which is the cable-code word for the American Red Cross, was selected as the name of the new ship as a compliment to the war work of the Red Cross. Miss Margaret Farrand, daughter of Dr. Livingston Farrand, chairman central committee, American Red Cross, was sponsor for the vessel.

Southern Surgeons Meet.—At the annual meeting of the Southern Surgical Association held in New Orleans, December 16 to 18, the following officers were elected: president, Dr. Willard Bartlett, St. Louis; vice presidents, Drs. C. Jeff Miller, New Orleans, and Edward G. Jones, Atlanta, Ga.; secretary, Dr. Hubert A. Royster, Raleigh, N. C. (reelected), and treasurer, Dr. Guy L. Hunner, Baltimore (reelected). Hot Springs, Va., was chosen as the place of meeting for 1920.

The Seessel Fellowships.—Yale University announces the two Theresa Seessel Research Fellowships to promote original research in biologic studies. These fellowships yield an income of \$1,000 each, and are open to men or women. Preference is given to candidates who have already obtained their doctorate, and have demonstrated, by their work, their fitness to carry on successfully original research of a high order. The holder must reside in New Haven during the college year from October to June. Application should be made to the dean of Yale University, before May 1, and should be accompanied by reprints of scientific publications, letters of recommendation and a statement of the particular problems which the candidate expects to investigate.

Child Surveys.—Special investigations made by the children's bureau of the U. S. Department of Labor in three American cities show how babies have suffered as a result of the advance in the price of milk. In Baltimore, of the 728 children between 2 and 7 years of age, only 29 per cent. are now having fresh milk to drink as against 60 per cent. a year ago; in Washington, half of those between 2 and 7 years of age, who were visited by the public health nurses were receiving no fresh milk to drink; and in New Orleans conditions were even worse. Studies of the type recommended by the chief of the children's bureau would seek to determine all a child's needs. They would be based on actual living conditions in various types of communities; and would accordingly have a practical and not merely a theoretical value. Through them mothers would obtain an authoritative statement concerning the basic needs of growing children, and communities would be given an insight into the way in which those needs may be supplied.

Bequests and Donations.—The following bequests and donations have recently been announced:

To establish and maintain a nurses' home and training school in connection with the Goshen, Ind., Hospital a bequest of \$65,000, by the will of Mrs. Laura A. Kindig, Goshen.

Washington University Medical School, St. Louis, \$300,000 to endow a department of pharmacology. Of this amount, one half was given by the General Education Board and the other half was raised by the medical school.

New York Post Graduate Medical School and Hospital, New York City, \$25,000, by the will of Frederick Meade.

Presbyterian Hospital, New York City, the residuary estate valued at \$500,000, at the death of his two sisters, by the will of Charles G. Thompson.

Grant Hospital, Chicago, a donation of \$50,000 toward the endowment fund; \$25,000 remitted from the Christmas sale at the Parkway Hotel, and an addition to the present nursery to accommodate twenty more beds, by Mrs. William C. Seipp.

Michigan Hospital and School for Crippled Children, \$1,100,000; for a new nurses' home, \$650,000; Children's Free Hospital, Detroit, \$125,000, and St. Vincent's Orphan Asylum, Detroit, \$75,000, a Christmas gift from Mayor James Couzens of Detroit.

FOREIGN

Deaths in the Profession Abroad.—Dr. E. J. Pontoppidan, professor of skin and venereal diseases at the University of Copenhagen and member of Danish, Swedish, Argentine and Italian dermatologic societies, elected at Rome in 1912 to preside at the Eighth International Dermatology Congress; surgeon in chief of the Rudolph Berghs Hospital; aged 72. —Dr. Raphaël Lépine of Lyons and Dr. C. Ladame, professor of psychiatry at the University of Geneva.

Semicentennial of Sainte-Beuve.—It is just fifty years since the death of Sainte-Beuve whose "Monday essays" in the Paris dailies are said to have been events of European importance. As our French exchanges are recalling, he was a physician before he turned to literature, and his training in psychology and biology helped to make him, as he was called, the world's greatest literary critic. It was Sainte-Beuve who said when some one remarked that charlatanism was everywhere, "Yes, in politics, in the art of governing mankind that is perhaps true. But in science, in art, the glory, the eternal honor is that charlatanism shall find no entrance; herein lies the inviolableness of that noble portion of man's being."

The Flemish Congress of Physicians and Naturalists.—The Amsterdam section of this Flemish association recently gathered at Antwerp for its first meeting since the beginning of the war. About thirty members were present, and Professor De Bruyne presided. Prof. F. Daels delivered an illustrated address on clinical cures of cancer. The members voted unanimously—four refraining from voting—to drop twenty-four members from the membership of the general association on account of pro-German "activism." The *Nederlandsch Tijdschrift* states that the assembly discussed the foundation of a Flemish medical journal, in connection with publishing the transactions of the congress, but no decision was reached.

Citations for Bravery.—The *Presse Médicale*, November 29, gives a long list of official citations of French medical officers for exceptionally devoted services during the war, and two American names are included in the list. The first is Dr. Lester Pratt, medical officer in the Fifth Regiment of Marines. He is stated to have had charge of an advanced station in Belleau Wood, June 11, 1918. "His post being exposed to a violent bombardment, he displayed remarkable self possession and devotion to duty." The other is Dr. Richard Shea, also a medical officer of the Fifth Regiment of Marines. "During the attack of Belleau Wood, he displayed extraordinary heroism, tending the wounded during a violent bombardment, June 11, 1918." The official notice of the citations in the French records is dated Oct. 15, 1919.

Tuberculosis and Housing.—The medical officer of health for the city of Edinburgh claims that statistics have clearly proved the close relationship which exists between tuberculosis and overcrowding. Out of 263 cases of tuberculosis notified in Scotland in 1914 and 1915, no less than 159 came from houses of one, two and three apartments. The old country cottages of Scotland are badly situated and very damp. Thorough ventilation is impossible, and, indeed, there is often scarcely any ventilation at all, the windows being so fixed that only one small pane can be opened. The situation is not very much better in England. Of the tuberculous persons visited in Somerset between 1913 and 1918 more than 40 per cent. were found to be sharing their bedrooms with other persons, and in less than 10 per cent. of all cases was it found possible to remedy this state of affairs at a later date.

Inaugural Exercises of the French University of Strasbourg.—A most imposing ceremony, historical pageant and general tribute ushered in the opening exercises of the University of Strasbourg under French rule November 21. The president of the republic and the three marshals of France took part in the festivities, as also delegates from many other universities in France and abroad. The dean of the university is Professor Weiss of the chair of biology. Other well known names on the medical faculty are Ambard (physiology), Duverger (ophthalmology), Forster (obstetrics), Masson (pathologic anatomy), L. Blum and Bard (clinical medicine), Chavigny (forensic medicine), Nicloux (biologic chemistry), Stolz and Sencert (surgery), and Pautrier (skin and venereal diseases). The French Académie de Médecine was represented by Professors Delorme, Netter and Schwartz.

LATIN AMERICA

No Examination Required for Uruguayans with Foreign Degrees.—The *Anales de la Facultad de Medicina* gives the text of the law recently enacted which abrogates the requirements hitherto prevailing in regard to reexamination on returning to practice in Uruguay after obtaining degrees in foreign countries from institutions that grade to correspond with the Uruguayan faculties.

Deaths in the Profession.—Dr. J. Lemos, a prominent bacteriologist and clinician of Mendoza, Argentina, chief of the local Asistencia Pública and of the Pasteur Institute. His antiserums and vaccines have been widely used. —Dr. L. J. Velarde, the veteran of the Argentine naval medical service in which he occupied various high posts, displaying great initiative and executive ability. —Dr. A. J. Drago, medical expert for the courts in Argentina and director in the Obras Sanitarias of the nation, aged 58. —Dr. Luis Manzone, a physician of San Isidro, Argentina, succumbed to pneumonia, November 3, aged about 60. —Dr. F. de Paula Valladares, professor of clinical surgery in the University of Rio de Janeiro, and head of a private surgical clinic, aged 67. —Dr. Ernesto Samit of Santiago, Chile, succumbed to typhus while combating the recent epidemic there. The obituary notices of him mention also the deaths in the prevailing epidemic of three other young physicians, two medical students, nine trained nurses and numbers of the personnel of the different hospitals.

Sexual Enlightenment.—The *Semana Médica* states that great interest has been aroused in the work of the Federación Abolicionista Internacional by the Argentine-Uruguay committee. This committee is organizing an extensive conference at Montevideo to discuss sexual hygiene and venereal prophylaxis. Dr. R. E. Baethgen will open the discussion on sexual enlightenment of the young; addresses will be given also by Dr. Paulina Luisi, secretary-general of the Argentine-Uruguay committee and school medical inspector, and by Sr. J. A. Seniliosa. The closing address will be by Dr. José Brito Foresti, president of the committee, professor of syphilography at the University of Montevideo.

Uruguay Remits Import Duties on Drugs for Treatment of Syphilis.—The *Boletín del Consejo Nacional de Higiene*, published at Montevideo, gives the discussion in the senate and the text of the law signed by the president, October 1, which remits all duties on the importation of the specific products which the Consejo Nacional de Higiene regards as efficacious in combating syphilis. The Asistencia Pública Nacional is authorized by the law to purchase the necessary quantity of drugs and to sell them at cost price to physicians and pharmacists on demand. Reserve supplies of not less than 10,000 doses are also to be kept on hand. The Consejo Nacional de Higiene is to fix the price for sale to the public; this price must not be more than 10 per cent. above the cost price.

The Conference on Tuberculosis at Rosario, Argentina.—A large gathering of persons especially interested in the campaign against tuberculosis was held recently at Rosario, and the important resolutions adopted are reproduced in a number of our South American exchanges and have been sent to us by the secretary general. A general outline for the whole work was drawn up, advocating a preventorium for each 100,000 inhabitants at least, with simple inexpensive sanatoriums for the curable tuberculous; enforcement of hygiene for foods, vehicles, etc.; better housing facilities, with penalties for owners of insanitary dwellings; enlightenment of the public, and the compulsory declaration of tuberculosis. The conference suggested that part of the income from the lottery be devoted to the prophylaxis of tuberculosis. One resolution urged that a commission of experts should be appointed to have exclusive charge of the whole system of antituberculosis prophylaxis and coordinate all efforts, with ample means at its disposal. Larroque's proposal for insurance against tuberculosis was adopted also, the expense to be borne by both workingman and employer, and special preventorium to be organized by the insurance societies. Another resolution urged that the state should interfere to enable workingmen to buy materials cheaply for home building. Other resolutions voted that vacation or colony schools should form an integral part of the public school system; that a premarriage certificate of freedom from serious disease should be enforced; that illiterate, new recruits should be taught to read, and that the army and navy should inaugurate a section for anthropometry. Other resolutions specified various desirable hygienic regulations.

Government Services

Appointment to Relief Commission

Walter P. Davenport, Major, M. C., U. S. Army, on duty with the American Committee for Relief of the Far East, Caucasus Branch, Tiflis, has been appointed medical advisor to the Interallied High Commissioner for the Caucasus. The commission is doing food and medical relief work in Armenia, Georgia and Azerbaijan.

Hospital Discontinued

Army General Hospital No. 7, Roland Park, Md., has been discontinued as a separate institution and will be maintained and administered as an annex from Subdivision of General Hospital No. 2, Fort McHenry, Md. The federal educational board and American Red Cross will maintain General Hospital No. 7 as a reconstruction school for disabled soldiers.

Army Medical Estimates

In the estimates submitted by the Army and Navy for the fiscal year ending June 30, 1921, about \$6,800,000 is asked for the medical department of the Army, including an outlay of \$500,000 for commencement of the structure of the army medical center at Walter Reed General Hospital, Takoma Park.

LONDON

Dec. 10, 1919.

The Prevention of Venereal Diseases

The National Council for Combating Venereal Diseases has issued a memorandum stating that the prevention of venereal diseases is a large sociomedical problem. In the direct line of attack, ample facilities for treatment and instruction of the public—both social and hygienic—occupy the first place. Concerning the question of personal disinfection after risk is taken, it is no part of the council's policy to conceal the truth, and it has always acknowledged the value of cleansing and disinfecting material, applied early and thoroughly, in diminishing risk. But abstention from exposure is the only certain safeguard. Continence is to be encouraged by every means and on every ground both social and hygienic. As no person who has indulged in promiscuous intercourse can be sure that he is not infected, he is bound in duty to himself and to society to seek means of cleansing at the earliest moment. For this purpose a thorough local application of soap and water is of the greatest value, followed (if possible) by the use of such disinfectants as may be recommended by a physician. While such applications, if properly used, do sensibly reduce the risk of disease, if applied within four hours of exposure, they afford no certain security. They do not in the slightest degree prevent the contraction of syphilis in other parts of the body (as the lips, face or hands) than those disinfected. Satisfactory self-disinfection of women is practically impossible, and skilled medical attention at the earliest possible moment is absolutely necessary. No one should be urged to arm himself in advance with a prophylactic packet.

This advice differs little from that of another organization, formed with the same object though differing somewhat in policy, the Society for the Prevention of Venereal Diseases, which has already been mentioned. This society (which consists mainly of leaders of the profession—Osler, Mott, Arbuthnot Lane, Rolleston and others) is inviting the public to become members at an annual subscription of \$5. All who are interested are asked, whether they become members or not, to send a stamped and addressed envelop, whereupon a leaflet giving the necessary instructions will be sent.

Report of Medical Officers of Board of Education

The annual report of the chief medical officer of the board of education, Sir George Newman, just published, is an important document in which future policy is outlined. In a section on "The Beginnings of Disease," Sir George says

that we are profoundly ignorant of this subject, but the school medical service gives an opportunity for examining "the nation in its childhood" and studying the earliest symptoms of disease, the importance of which has been so much insisted on by Sir James Mackenzie. A scheme for investigation of symptoms on a national scale is sketched. Beginning with the antenatal clinic, which the board of education supports in some measure, the work is to be continued through the school for mothers, the infant clinic, the day nursery and the nursery school to the secondary school and finally into the sphere of industrial employment. The observations are to be continuous and handed on from place to place with the child. Coincident with this work, efforts will be made to improve the health and physique of the child "other than by medical treatment. Playgrounds and playing fields, physical culture and games are to be provided and their effects noted.

As to the present condition of schoolchildren: In 1917 the death rate per thousand living was 94 for children under 1 year of age, 29 between the ages of 1 and 2 years, 13 for children aged 2 to 3, 8 for children aged 3 to 4, and 6 for children aged 4 to 5. One of the chief defects noted in "entrants" is malnutrition, expressed either as lack of growth or as rickets and dental defects. From 2 to 3 per cent. of entrants show a serious degree of rickets. Many districts have 60 per cent. of dental caries. Next in importance come infective diseases—measles, whooping cough, tuberculosis and rheumatism. From 50 to 60 per cent. of the entrants have suffered from measles, which leave behind ailments which cause prolonged or permanent disablement. Finally there are catarrhal conditions, which undermine the health and physique of the child and predispose to and create a nidus for various forms of permanent disease. It is these beginnings that must be attacked first by discovery and then by treatment. Both the normal and the abnormal child must be studied. "Why is this child normal? Has it had measles, adenoids, rickets, tuberculosis or rheumatism? If not, why not? If so, how has it overcome these maladies and escaped their sequelae? The answer is of the first importance to the child, to other children, to science, and to the national well-being."

The number of children in average attendance at school during 1917-1918 was 5,194,493. The number medically inspected during the year ending December 31 was 1,317,657. Compared with 1917 there was a great improvement in cleanliness, but the condition of the teeth was not so good. There are now 465 special schools for defective children accommodating 34,478. Defectives are estimated as follows: cripples, 34,500; mentally defective, 30,800; deaf and dumb, 5,500; blind, 4,250. Thus accommodation has not been provided for more than half of the defective.

Australasian Medical Congress for Queensland

The Australian federal authorities have announced that after an interval of six years, the Australasian Medical Congress will meet in Brisbane in August, 1920. At the 1911 congress, held in Sydney, it was decided to recommend the federal government to increase the funds for an Australian institute of tropical medicine, so as to enable an organized inquiry to be made into matters relevant to the permanent settlement of tropical Australia by the white race. The federal government, when approached, made a permanent subsidy for this purpose, with the result that much good work has been done. At the congress next year the principal item for discussion will be the white settlement of tropical Australia. Other matters for consideration are the doctors and lodges' dispute, the control of venereal disease, military surgery, and hygiene, in the light of war experience, and the adjustment of health administration as between the commonwealth and the states. All the states and New Zealand will be represented at the congress.

Sir Auckland Geddes' Criticism of the Medical Profession

Sir Auckland Geddes, president of the board of trade, who, it may be remembered, is a qualified physician and was professor of anatomy in McGill University, in an address to the students of Charing Cross Hospital on the occasion of the annual presentation of prizes, delivered some severe criticisms of the profession. It was extraordinarily unequal not only in its technical knowledge but also in its public spirit. The glorious record of the profession in the war was won by a minority. A large number were now sharing in the glory who had done nothing to help. He had taught at a good many medical schools and therefore knew how limited was the outlook of the profession. What was passing for medical education in some schools was really

only technical instruction with very little education about it. Men from schools where that type of mind predominated failed to rise to the occasion when the time came. All, whether teachers or students, should get clearly into their minds the difference between technical instruction in the medical schools and the educational side. Because of the state of the educational side for twenty years before the war, we witnessed some of the deplorable exhibitions during the war. There were three great emotions in every human being—the appreciation of beauty, the desire to serve one's generation, and the desire to know the truth. It was in relation to these three great emotions that the medical school was lax. On those sides they saw most in national service (Sir Auckland Geddes was minister of national service in the war), and they had found in the medical service a less satisfactory development than in some others.

As might be expected, this criticism has proved unpalatable to the profession. In a press interview published in the *Daily Chronicle* Dr. Cox, medical secretary of the British Medical Association, said that Sir Auckland Geddes' statement was in conflict with the opinion of men in as good a position to judge the work of medical service. "The medical service has been consistently praised and its work compared with that of other branches of the army." Physicians won 5,227 war decorations. Of these ten were V. C.'s (the most coveted decoration in the British army). More than 11,000 civilian physicians were passed into military service. Dr. Cox shared Sir Auckland's dissatisfaction with medical education, but his remarks did not apply only to it. All education was inferior to what it ought to be.

British Science in the War

At the anniversary dinner of the Royal Society, the president, Sir Joseph J. Thompson, O.M., in replying to the toast of the society, said that there was no country, excepting France, in which men of science threw themselves with such ardor as in this country into making researches which would benefit our troops at the front—certainly not Germany. One remarkable fact that stood out in this war was that every branch of science had its application in the service and defense of this country and was superior to that of our enemies. There had been nothing more conspicuous in the war than the triumph of medicine. They had made up leeway in the war, but it took them five years of suffering and sorrow and loss. That period would have been shortened if the nation before the war had been alive to the part which science must play in any war and had provided departments in which the development of the science of war could have been worked out under more favorable conditions. If they had had such departments, many requirements would have been anticipated.

PARIS

Nov. 27, 1919.

Death of Prof. Raphaël Lépine

French medical circles have suffered a great loss in the person of Professor Lépine, who died at Menton, November 17, in his eightieth year. Raphaël Lépine was born at Lyons in 1840, where he pursued his classical studies. His medical studies were also begun here. After having been intern at the Hôpitaux de Lyon for four years, he came to Paris, where he secured an internship in the Hôpitaux de Paris in 1865. Here he became a pupil of Charcot. In 1867 he studied in Berlin and later (1869) in Leipzig in the laboratory of Ludwig, where he made the interesting discovery of the vasomotor nerves of the tongue. On his return from Germany he entered the service of Brown-Séquard. In 1872 he became clinical chief, and in 1874 physician to the Hôpitaux de Paris. The following year he was appointed agrégé professor on the Paris Faculty of Medicine. Two years later (1877) he secured the chair of clinical medicine at the Lyons Faculty of Medicine. In 1888 Lépine was chosen correspondent of the Academy of Medicine, and in 1896 he was elected *associé national*. He was likewise correspondent of the Academy of Science. Dating from his stay in Paris he had been vice president of the Société de biologie. In 1905 he was chairman of the Congrès français de médecine. He was repeatedly chosen delegate of the French government at the Congrès internationaux de médecine.

Being at once clinician and physiologist, Professor Lépine constantly pursued parallel clinical and experimental researches. He published numerous works on diabetes, its complications and treatment; on kidney diseases, etc. He was an active collaborator of the *Semaine médicale*, in which

he published many valuable essays on therapeutics, among others, one entitled, "Doit-on traiter la fièvre?" which constituted his report on this subject to the therapeutic section of the thirteenth Congrès international des sciences médicales, held in Paris in 1900.

In collaboration with Bouchard, Charcot and Vulpian, Lépine founded the *Revue mensuelle de médecine et de chirurgie* (1877), which in 1880 was segregated as the *Revue de médecine* and the *Revue de chirurgie*. Lépine remained one of the directors of the *Revue de médecine* up to the time of his death.

Lépine's hospital service and scientific researches did not absorb all his time and attention. He was far from indifferent to the great social problems of his day. He was president of the Lyons chapter of the Ligue des droits de l'homme from its foundation in 1898 until 1903.

Strasbourg University Festival

The reopening of the University of Strasbourg was recently celebrated with great enthusiasm. The president of the republic delivered an important address, in which he alluded to Pasteur, who, at the height of his fame, spoke feelingly of the course in chemistry that he took at the Ecole de pharmacie de Strasbourg and at the Faculté des sciences during the years 1848-1852. The president expressed his approval of the idea of forming a Société des amis de l'Université de Strasbourg, analogous to the Société des amis de l'Université de Paris. The object of such a society will be to aid in the establishment of professorial chairs, a wide range of courses and lectures, and in the more extended equipment of the laboratories and libraries. It is also hoped to found certain prizes to encourage study in certain fields, and to establish scholarships and traveling fellowships.

Concurrently with the celebration of the reopening of the university, the eighth Congrès des étudiants was held in Strasbourg, at which the chief topic of discussion was the devising of ways and means to bring about a betterment in the moral and physical life of students. American, Belgian, Dutch, English, Italian, Norwegian, Polish, Swiss and Czechoslovak delegations were present at the congress.

Personal

Dr. Cunéo, agrégé, has been appointed professor of medico-surgical anatomy on the Paris Faculty of Medicine.

Dr. Pinard, formerly professor of clinical obstetrics on the Paris Faculty of Medicine, who was a candidate at the parliamentary elections, as I mentioned in my letter last week, has been elected a member of the chamber of deputies.

Marriages

HARRY EVANS TRIMBLE, Asst. Surg., U. S. P. H. S., to Miss Agnes Evelyn Malley of St. Paul, at Washington, D. C., December 18.

CHARLES THOMAS MAXWELL, Sioux City, Iowa, to Miss Nelontine Jane Alderson of Russellville, Ky., November 22.

CHARLES HAMILTON HARBAUGH, Philadelphia, to Miss Minnie Anna Moore Hall of Hayfield, Va., December 11.

WILLIAM OSCAR OTT, Rochester, Minn., to Miss Maggie Jane Smith of Lexie, Miss., December 7.

STANLEY ERNEST CRAWFORD, Pittsburgh, to Miss Caledonia Stroud of Franklin, Va., December 6.

LIONEL FRANCIS LORIO, Lakeland, La., to Miss Marie L. Green of Lottie, La., December 4.

FOWLER BURDETTE ROBERTS, Akron, Ohio, to Miss Marie dePaul of Chicago, November 1.

JAY DEVER LINTON to Dr. Nellie Cameron Craig, both of Philadelphia, December 20.

HARRY AUGUST NAUMER to Miss Anna Alvira Risch, both of Brooklyn, December 13.

FRANCIS WELD PEABODY, Boston, to Miss Virginia Chandler of Chicago, December 18.

HYMAN GREEN, Boston, to Miss Leona Freedman of Brookline, Mass., November 11.

JOHN CHARLES MAHR to Mrs. Ollie Dunn, both of Oklahoma City, December 11.

ALBERT JACOB MISHKIND, Denver, to Miss Mollie Ettelson of Chicago, December 17.

Deaths

Sir William Osler, Regius professor of medicine in the University of Oxford, England, whose seventieth birthday was chronicled in THE JOURNAL of July 12, 1919, died at his home in Norham Gardens, Oxford, December 29, from pneumonia.

Dr. Osler was born in Tecumseh, Ont., the son of Rev. F. L. and Ellen Frere Osler. He received his preliminary education in Trinity College School, Trinity College, Toronto, and the Toronto University, and took his medical course in McGill University, Montreal, from which he was graduated in 1872. His graduation thesis on topics in pathologic anatomy was awarded a special prize, "because it was greatly distinguished for originality and research."

On his return after two years of study abroad Dr. Osler began to teach pathology in his alma mater. He was made professor of the institutes of medicine of McGill University in 1874, and remained in this position until 1884, when he accepted the professorship of clinical medicine in the University of Pennsylvania, Philadelphia. In 1889 he became professor of principles and practice of medicine in Johns Hopkins University, Baltimore, leaving this position in 1905 to become regius professor of medicine at Oxford.

In 1911 he was created a baronet of the United Kingdom, by King George V. He was deservedly honored by many universities and scientific bodies. He received the honorary degree of LL.D. from McGill University in 1895, the universities of Aberdeen and Edinburgh, in 1898; University of Toronto, 1899; Yale University, 1901; Harvard University, 1904, and Johns Hopkins, 1905; the degree of Doctor of Civil Law from Trinity University, Toronto, in 1902, and the University of Durham in 1913; the degree of Doctor of Science, from Oxford University in 1904, Liverpool University in 1910, and the University of Dublin in 1912. He was made a fellow of the Royal College of Physicians in 1883, and a fellow of the Royal Society in 1898.

Dr. Osler was an accepted authority in medical science, and as a teacher he aroused affection and enthusiasm in his students. The model medical clinic which he organized at Johns Hopkins was the first of its kind in this country, and in this clinic were trained many medical students and young physicians for higher work in clinical medicine, inspired by Dr. Osler's example and precepts. His literary work was of a high degree of literary and scientific merit, and was always inspired by lofty ideals. His literary works comprise 730 titles, chief among which were his *Principles and Practice of Medicine*, which appeared in 1892, and the encyclopedic *Modern Medicine*, of which he was coeditor.

Dr. Osler was taken ill with pneumonia in November, and later was reported to be convalescing; but pleurisy with effusion developed, necessitating a thoracentesis. On Christmas day he sent a typically cheerful telegram to Johns Hopkins Hospital, announcing that he was making a good fight; three days later he died. He is survived by his wife; his only son died while on active service in the war.

Thomas Terrell Jackson ☉ San Antonio, Texas; University of Texas, Galveston, 1893; aged 51; president-elect of the State Medical Association of Texas; division surgeon of the Southern Pacific System; formerly president of the Bexar County Medical Society and Western Texas Medical Association; formerly secretary of the State Board of Medical Examiners, and a member of the State Board of Health; formerly president of the board of directors of the Southwestern Insane Hospital, San Antonio; a member of the San Antonio Board of Health, and health officer of Bexar County; captain and assistant surgeon, United States Volunteers, during the War with Spain; and major, M. C., U. S. Army, during the world war, and honorably discharged, Dec. 4, 1918; died December 12, from heart disease.

Charles Henry Cook ☉ Natick, Mass.; Bellevue Hospital Medical College, 1875; aged 74; a trustee of the Leonard Morse Hospital, Natick, since its organization in 1893; a member of the Massachusetts Board of Registration since 1909, and first president of the Federation of State Medical Boards of the United States, serving from 1913 to 1916; died December 3, from cerebral hemorrhage.

Daniel Eli Haag, Liberty Center, Ohio; Cincinnati College of Medicine and Surgery, 1880; aged 84; for many years professor of materia medica and therapeutics and dean of the faculty of the Toledo Medical College, and president of

☉ Indicates "Fellow" of the American Medical Association.

the board of trustees of Robinwood Hospital, Toledo; president of the Liberty State Savings Bank; died December 9, from heart disease.

Paul Gillespie • Wyoming, Ohio; Miami Medical College, Cincinnati, 1897; aged 48; local surgeon of the Cincinnati, Hamilton and Dayton Railroad; while driving his automobile over a grade crossing at Hartwell, December 15, was struck by a Baltimore and Ohio train, and sustained injuries from which he died a few hours later in Christ Hospital, Cincinnati.

Alexander James Connell • Scranton, Pa.; Bellevue Hospital Medical College, 1877; aged 63; attending surgeon to the Moses Taylor Hospital, Scranton, since 1889; surgeon and chief of staff and a member of the board of trustees of the State Hospital of the Northern Anthracite Coal Region of Pennsylvania, Scranton; died December 18.

Clarence W. Schaeffer • Philadelphia; Medico-Chirurgical College of Philadelphia, 1907; aged 34; diagnostician for the board of health for diphtheria and scarlet fever, and a member of the staff of the Lankenau, Episcopal, and Pennsylvania hospitals; died, December 19, from heart disease.

William McCarroll • Pontiac, Mich.; University of Michigan, Ann Arbor, 1881; aged 65; one of the organizers of the Oakland County Medical Society, and its president in 1906; one of the organizers and secretary of the Pontiac Medical Society in 1901; died December 12, from pernicious anemia.

Benjamin F. Gardner, Bloomsburg, Pa.; Medical College of Virginia, Richmond, 1865; aged 83; a member of the Medical Society of the State of Pennsylvania; a surgeon in the Confederate service during the Civil War; died at the home of his daughter, December 5, from senile debility.

Percy C. Hoskins • West Chester, Pa.; Jefferson Medical College, 1875; aged 66; once president of the Chester County Medical Society; a member of the staff of the Chester County Hospital and physician to the Smith Memorial Home; died in the Chester County Hospital, December 13.

Paul Rühnke Lanz • Oakland, Calif.; University of California, Berkeley, and San Francisco, 1899; aged 44; who was awaiting trial on the charge of forging names to prescriptions for narcotics; was found dead in the Hotel Herrick, San Francisco, December 8.

William Bayles VanDuyn, Trenton, N. J.; University of the City of New York, 1866; aged 79; a veteran of the Civil War, and later surgeon, U. S. Army, from which he resigned in 1880; surgeon for the police and fire department of Trenton since 1888; died December 6.

James Van Siclen Woolley, New York City; University of the City of New York, 1868; aged 76; attending surgeon to the Northeastern Dispensary, New York City, since 1870, and visiting physician to the Presbyterian Hospital since 1874; died December 14.

Ormond Willis Murphy, Vancouver, B. C.; Queens University, Kingston, Ont., 1909; aged 38; while driving in his automobile over a grade crossing near Beaconsfield Station, December 6, was struck by an electric railway freight train and instantly killed.

Erastus Van Hood • Ocala, Fla.; College of Physicians and Surgeons, Baltimore, 1884; aged 58; a medical officer during the Spanish-American War; for several years a member of the State Board of Medical Examiners; died December 5.

Melvin H. Turner • Ticonderoga, N. Y.; Albany (N. Y.) Medical College, 1873; aged 57; once president of the village of Ticonderoga; died in Moses Hospital, Ticonderoga, December 12, after two operations for carbuncle.

Giuseppe Dalla-Chiara, New York City; University of Turin, Italy, 1892; aged 53; died in Presbyterian Hospital, New York City, December 15, from carcinoma of the lungs and bronchial tubes.

Florence Nightingale Ferguson Ward, San Francisco; Hahnemann Medical College of the Pacific, San Francisco, 1887; professor of obstetrics in her alma mater; aged 59; died December 15.

John Holloway Pratt • St. Stephens, S. C.; Medical College of the State of South Carolina, Charleston, 1909; aged 44; was shot and killed in an affray near St. Stephens, December 14.

Francis Marion Elliott, Aurora, Ill.; Rush Medical College, 1869; aged 75; a member of the staff of the Aurora City Hospital and St. Charles Hospital, Aurora; died December 9.

John Louis Metzger, Jr., Philadelphia; Hahnemann Medical College, Philadelphia, 1912; aged 29; died in the Hahnemann Hospital, Philadelphia, December 9, from heart disease.

Millard F. Gerrish • Seymour, Ind.; University of Pennsylvania, Philadelphia, 1881; aged 63; secretary of the Seymour board of health; died December 16, from heart disease.

Richard C. Mackey, Hobart, Ind.; Loyola University, Chicago, 1883; aged 57; a member of the Indiana State Medical Association; died December 1, from cerebral hemorrhage.

Stephen D. Yerrington, Bailey, Mich.; Michigan College of Medicine and Surgery, Detroit, 1899; aged 73; died at Grant, Mich., November 27, from valvular heart disease.

John T. Townley • Milwaukie, Ore.; University of Oregon, Portland, 1906; aged 50; for many years a practitioner of Portland; died December 9, from arteriosclerosis.

Van Buren Newman, Tilden, Ky.; Miami Medical College, Cincinnati, 1872; aged 80; died at his country home in Henderson County, December 7, from senile debility.

Samuel Augustus Wood, Elmhurst, L. I., N. Y.; College of Physicians and Surgeons in the City of New York, 1879; aged 64; died December 12, from heart disease.

John E. Haggerty, Jr., New York City; Eclectic Medical College of the City of New York, 1911; aged 43; died December 18, from pneumonia.

Henrietta Eason Holbrook, Lebanon, Ohio; University of Nashville, Tenn., 1899; aged 59; died in an infirmary in Mobile, Ala., December 6, from tuberculosis.

John Edgar Crawford, Ray, Ariz.; Western Pennsylvania Medical College, Pittsburgh, 1905; aged 39; died at the home of his brother in Crafton, Pa., December 14.

Francis R. Stone, Savannah, Ga.; Savannah, Ga., Medical College, 1860; aged 83; surgeon in the Confederate service during the Civil War; died December 9.

William Bruce Stricker • Nanticoke, Pa.; Medico-Chirurgical College of Philadelphia, 1901; aged 42; died November 18, from pneumonia.

William P. Hanna, Lafayette, Ind.; Jefferson Medical College, 1877; aged 69; died in his apartment, December 13, from cerebral hemorrhage.

John Gray Blount • Washington, N. C.; Bellevue Hospital Medical College, 1892; aged 49; died December 8, from cerebral hemorrhage.

Chester Jennings, Little Rock, Ark.; Tulane University, New Orleans, 1883; aged 61; died December 11, from bronchial pneumonia.

Charles H. Janney, Washington, D. C.; University of Maryland, Baltimore, 1885; aged 57; died December 4.

SIR WILLIAM OSLER, 1849-1919

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

"ANTI-PNEUMOCOCCIC OIL" AND THE USE OF CAMPHOR IN PNEUMONIA

Report of the Council on Pharmacy and Chemistry

The Council has adopted and authorized publication of the report which appears below. This report declares "Anti-Pneumococcic Oil" (a solution of camphor in oil sold by Eimer and Amend, New York) ineligible for New and Non-official Remedies because (1) the recommendations for its use in pneumonia are not warranted by the evidence, (2) the name is not descriptive of its composition but is therapeutically suggestive, and (3) the sale of a solution of camphor in oil under a name nondescriptive of its composition is unscientific and a hindrance to therapeutic progress.

W. A. PUCKNER, Secretary.

The Council having decided to consider Anti-Pneumococcic Oil (Eimer and Amend, New York), the preparation was assigned to the Committee on Therapeutics for report. The report that follows was made by a member of this committee:

According to the advertising, Anti-Pneumococcic Oil is a "twenty-five per cent. solution of camphor in a thin oil" which was "originated" by August Seibert, M. D. The following directions are given for its use:

"10 c.c. (150 minims) to every 100 pounds of body weight, to be injected hypodermically every eight to twelve hours in pneumococcic pneumonia, as soon after the initial chill as possible."

It is claimed that the prescribed dose one hour before general anesthesia begins, "safeguards against postoperative pneumonia," and, that "animals can so be immunized against later and otherwise fatal intravenous pneumococcic infection (Boehnke, Institute for Experimental Therapy, Frankfurt)." The advice is given:

"In pneumococcic meningitis, endocarditis and pleuritis, 3% of salicylic acid should be added to this oil."

In an article by Seibert, "Camphor and Pneumococci" (*Medical Record*, April 20, 1912), a reprint of which is used to advertise Anti-Pneumococcic Oil, previous work (*München. med. Wchenschr.*, No 36, 1909) is mentioned as the starting point for the use of camphor in pneumonia. In this article, the author reports his first case, that of a young woman who entered St. Francis' Hospital on the third day after the initial chill "with the symptoms of severe toxemia (unconscious, temperature 105.5 F., pulse 130, and respiration 40) and involvement of both lower lobes." "Large doses of camphor," 12 c.c. of a 20 per cent. solution, were injected hypodermically "every twelve hours, resulting in gradual improvement and recovery by the fourth day, without a crisis." Seibert reports success in its use in twenty-one cases, but gives no case histories or protocols. He admits, however, that in four out of sixteen cases, following the first twenty-one so reported certain "limitations of this treatment were observed," and a "sudden rise of temperature in two patients on the second and third days of treatment, respectively, proved to be due to pneumococcic nephritis, promptly subdued by appropriate doses of urotropin, while the camphor injections were continued and resulting in speedy recovery." He further admits that empyema occurs, and states: "This proves that the camphor brought into the blood cannot prevent the as yet living organisms, constantly entering the blood current from the affected alveoli, from colonizing in the renal and pleural tissue."

He reports, among thirty-seven patients treated in this manner, one death, that of a man 68 years old, weighing 200 pounds, with a fatty heart. Heart failure was the real

cause of death. Seibert also reports some very incomplete experimental work; Dr. Hensel, assistant and pathologist of the German Hospital, found that "10,000 part of camphor added to the usual culture media inhibited the growth of pneumococci, while the controls all thrived"; Dr. J. C. Welch, pathologist of the Lying-In Hospital, found that rabbits infected with lethal doses of pneumococcus cultures intravenously were saved by large doses of camphorated oil; fragmentary protocols are given. The assistant pathologist of St. Francis' Hospital carried on the experimental work, adding salicylic acid to the camphor. No blood cultures are reported. The conclusion reached by Dr. Seibert is that salicylic acid up to 3 per cent., added to the camphorated oil, is effective in preventing pleural infection. In the article by Dr. Seibert, there appear most sketchy reports of cases, recovery being reported without crisis in from three to nine days.

The referee has made a careful search of the literature, with the following results: Boehnke (*Berl. klin. Wchenschr.* 50:818, 1913), using white mice, failed to confirm the experiments reported in Seibert's paper, unless camphorated oil were given before the pneumococci, and even then, he felt that the results were too irregular to be of great significance. When given with anti-pneumococcic serum, however, he felt that there was some benefit to be seen by the administration of camphor; his protocols, however, are not detailed. There is no report of blood cultures, etc.

Another worker, H. Leo (*Deutsch. med. Wchenschr.* 39:690, 1913), reported that camphor water given intravenously prolonged the lives of thirty-eight rabbits inoculated with pneumococci. Here again there were no adequate protocols and very little evidence of careful experimental work appears.

In the literature of the past ten years, there appear sketchy clinical articles on the value of huge doses of camphor in pneumonia. Markevitch (*Russk. Vrach.*, June 27, 1914; abstr., *THE JOURNAL*, Dec. 5, 1914, p. 2081) treated 226 cases of pneumonia with 5 c.c. of camphorated oil hypodermically four times daily, at the same time giving digitalis (amount not stated), with a mortality of 6.6 per cent., whereas, in 322 cases untreated, there was a mortality of 13.3 per cent. He reports 133 grave cases; sixty-six received no camphor; 48 per cent. died. Of sixty-seven treated with camphor, only 22 per cent. died. He reports temperature falling by lysis when camphor is used, and comments on the symptomatic improvement following its use. With the great variation in the clinical course of pneumonia, the above figures, though suggestive, certainly need further support before the routine use of camphor as recommended by Seibert can be sanctioned.

Later articles found on the subject refer to it in a very cursory way, giving no protocols and no cases, and giving the referee the feeling that the conclusions were very impressionistic.

RÉSUMÉ

After careful search of the literature, the referee concludes that: Huge doses of camphor, to 250 grains in twenty-four hours, may be given to man without serious results. No satisfactory evidence, however, appears that camphor has a specific germicidal action on pneumococci (similar to that of ethylhydrocuprein). The clinical evidence, as found in the literature, is certainly of very little value. It appears that the sale of a simple solution of camphor in oil under the guise of "Anti-Pneumococcic Oil" is to be deplored (a 20 per cent. solution of camphor in cottonseed oil is official in the U. S. Pharmacopeia as camphor liniment). It is recommended that the preparation be held inadmissible to New and Nonofficial Remedies because exaggerated therapeutic claims are advanced for it, and because the name is not descriptive of the composition, but is, instead, therapeutically suggestive.

Health First Means Safety First.—Eyestrain is a cause of headache and general bodily fatigue which could be eliminated with but little expense or loss in time and with an obviously great reduction in the amount of accidents.—*Minnesota Health J.*, Nov. 20, 1919.

"ALLEGED PLACENTAL FUNCTIONS"

To the Editor:—In an editorial comment (THE JOURNAL, Dec. 6, 1919, p. 1774), based largely on certain clinical observations recorded by Hammett and McNeile, your conclusions appear to be that we must "hesitate to give the placenta a place in endocrinology." I heartily concur with the display of such a laudable spirit of conservatism in the new and untried field of endocrinology, in which the tendency has been to allow speculation to outrun discretion. However, neither in Hammett's articles (let me instance the one on the "Function of the Internal Secretion of the Placenta," *Endocrinology* 3: 307 [July-Sept.] 1919, which contains a summary of his work) nor in your comment has the evidence of the endocrine function of the placenta been favorably presented. The difficulties confronting research on this problem, because of the presence of ovaries and fetus, are numerous and baffling, and until recent years little progress had been made:

1. The earlier work of Veit and his successors who attempted by means of precipitin, complement fixation and similar tests to prove that eclampsia is due to an overwhelming of the maternal organism by foreign (placental) protein has been discredited, although the hypothesis has not been disproved.

2. The researches of Lane-Clayton and Starling and of others dealing with the growth of the breasts during pregnancy were performed with aqueous extracts of the placenta which contain none of the active principle, or mere traces of it. Moreover, these investigators were unaware of the cyclic changes occurring in the breasts during rut and were misled by these periodic changes, as Unger and I pointed out (*Arch. Int. Med.* 7: 812 [June] 1911).

3. Not until extracts prepared by extracting placental material with lipoid solvents had been used (Iscovesco: *Compt. rend. Soc. de biol.* 73: 104, 1912. Aschner: *Arch. f. Gynäk.* 99: 534, 1913. Herrmann: *Monatschr. f. Geburtsh. u. Gynäk.* 51: 1, 1915. Frank and Rosenbloom: *Surg. Gynec. & Obst.* 21: 646 [Nov.] 1915) were the results positive or concordant. The positive results were due to the greatly increased concentration of the active substance which is present in minute quantity only in the fresh placenta.

4. The problem is still further complicated by the fact that the corpus luteum of the pregnant ovary contains an active principle which acts similarly on the breasts (and uterus) to the substance contained in the placenta. So far as studied, a close biologic identity exists between these two substances (Frank: *Surg. Gynec. & Obst.* 25: 329 [Sept.] 1917). For that reason, experiments dealing with breast hyperplasia must be conducted not only on virgin animals but also on animals castrated before their first rut (compare paragraph 2). As an additional precaution, at least one breast should be removed and kept for control before beginning the experiment.

5. A sharp distinction must be drawn between the physiologic growth of the glandular structures of the breast during pregnancy (hyperplasia) and the post partum secretory activity of the fully formed gland. This question was discussed by me as early as 1912 (*Arch. f. Gynäk.* 97: 183, 1912), as the distinction between substances causing breast hyperplasia and galactagogues was already frequently lost sight of. Hammett appears to have fallen into the same error. "In an experiment carried on at the Boston Lying-In Hospital during the winter of 1917-1918, it was impossible to detect by bedside observation [the italics are mine] an increased growth of mammary tissue when desiccated placenta was fed post partum to lactating women, as compared with a series of patients not receiving the placental material" (Hammett: *Endocrinology* 3: 307 [July-Sept.] 1919). Post partum, let it be understood, the mammary gland has reached its maximum development and is not amenable to further stimulation (the increasing refractoriness to stimulation, as the physiologic maximum is approached, has been mentioned

by me in the *Journal of Cancer Research*, Proceedings of the American Association for Cancer Research. 2: 515, 1917). Moreover, bedside observations do not lend themselves to delicate quantitative determinations. The question as to whether placental extracts exert a galactagogue action is quite distinct from the question of placental internal secretory activity. With Halban (*Arch. f. Gynäk.* 75: 353, 1905), I believe that the placenta inhibits milk secretion. The infinitesimally small amount of active substance contained in 10 grains of desiccated placenta, as given by Hammett, is far too small to produce such an effect, were it obtainable, particularly when introduced by mouth.

6. The report of Hammett that "it is evident that there is produced in the placenta some substance capable of acting as a stimulus to growth, when ingested by the mother and passed on to the infant in the lacteal secretion . . ." need not be dilated on in this connection. This is a question for pediatricians and food experts to settle from the clinical standpoint, but cannot be proved or disproved by means of infants observed under the varying and uncontrollable conditions existing in the best conducted maternity hospital; nor is an observation period of two weeks sufficient to permit the drawing of conclusions. To apply these observations to the fetus in utero is even more unjustified.

7. The evidence in favor of considering the placenta as a true gland of internal secretion may be thus indicated, in bare outline: By extraction of placental substance with lipoid solvents, a viscid concentrate is obtained which is thermostable and resists fairly concentrated acids and alkalis. When it is injected subcutaneously into virgin immature castrates (rabbits show the changes most conclusively, but guinea-pigs, white rats and female dogs also react positively), rapid hyperplasia of the uterus and breasts results. On withdrawal of the extract, both uterus and breasts (the latter mainly in their acinous structures) regress. Colostrum then appears in the breasts, if the stimulation has been carried to the proper degree of development, in from three to seven days after conclusion of the injections. (For a short outline, the reader may consult Frank: *The Placenta Regarded as a Gland of Internal Secretion*, *Surg. Gynec. & Obst.* 25: 329 [Sept.] 1917.)

8. As stated in the article just referred to, the possibility cannot be denied that the active substance originates in the corpus luteum of pregnancy, and is merely stored in the placenta. Against this hypothesis, the fact that only minute amounts occur in the placenta, and that when inaugurated, the changes continue in spite of castration, must be weighed.

No experiments have been performed to determine whether the placenta of animals castrated during pregnancy contains less of the active substance, nor would such experiments prove conclusive even if exact quantitative methods of extraction were at our disposal. Therefore, the origin of the active substance obtained from the placenta must at present be ascribed to this temporary but important gland.

ROBERT T. FRANK, M.D., New York.

"ACUTE ABDOMEN"

To the Editor:—In reply to Dr. M. W. Lyon, Jr., whose letter (THE JOURNAL, Dec. 20, 1919, p. 1897) takes issue with the designation "acute abdomen": The reference is to a report of remarks by Dr. Deaver. I wish to refer to the usage of the same terminology by Dr. Charles L. Gibson of New York, whom every Cornell student remembers as a purist in surgical nomenclature. Lymph glands exist for some surgeons, but only lymph nodes for Dr. Gibson. My own memories of the course in medicine at Cornell include none more vivid than Dr. Gibson's "Please do not say 'lymph glands' in my clinic!" Did a student mention carcinomas or sarcomas? He learned instantly that he meant carcinomata or sarcomata. Let a student, demonstrating on a patient, say to Dr. Gibson "And here is your adenitis," and the response would inevitably be "Not my adenitis!"

This is submitted as evidence that Dr. Gibson is untiring in his efforts to instill into his students a sense of accuracy in nomenclature. Therefore, when he begins his lectures in

surgery with "Acute abdominal disease—the so-called 'acute abdomen,'" it is my own feeling that "acute abdomen" has the endorsement of usage by a past master of terminology. Dr. Gibson's syllabus of lectures, open before me as I write, begins:

A. ACUTE ABDOMINAL DISEASE
"ACUTE ABDOMEN"

The quotation marks that indicate Dr. Gibson's attitude toward the term that he uses with this qualification were omitted from the report of Dr. Deaver's remarks referred to before. I cannot refer at the moment to any writing of Dr. Deaver's that will show whether he uses quotation marks as does Dr. Gibson. At all events, with or without quotation marks, "acute abdomen" gives the impression of a condition for which something should be done in a hurry; and I do not feel that it is advisable to adopt a longer terminology even as a concession to purity of diction.

RAMSAY SPILLMAN, M.D., Washington, D. C.

Dr. Spillman's letter was referred to Dr. Lyon who replies:

To the Editor:—Dr. Spillman's chief argument for the employment of "acute abdomen" seems to be that it has the sanction of Dr. Charles L. Gibson, an undoubted purist as shown by several examples. The fact that Dr. Gibson uses the term within quotation marks is an admission that the expression is irregular. I see no special objection to using it with quotation marks. Like "T. B. bugs," "beasts" as applied to protozoa, and "shots" of bacterins, such expressions as "acute abdomen, acute appendix, chronic appendix," etc., would be better confined to familiar conversations than be used in formal speech or publication.

The Century Dictionary defines acute as follows: "1. Sharp at the end; . . . 2. Sharp or penetrating in intellect; . . . 3. Manifesting intellectual keenness or penetration; . . . 4. Having nice or quick sensibility; . . . 5. Keen; sharp; intense; poignant: said of pain, pleasure, etc. 7. In *pathol.* attended with more or less violent symptoms and coming speedily to a crisis: applied to a disease: as an acute pleurisy: distinguished from subacute and chronic." Such definitions scarcely apply to the human abdomen. With respect to the seventh definition it must be borne in mind that the abdomen is not a disease and that the abdomen does not have symptoms although diseases of the abdomen are characterized by symptoms.

"Acute abdomen" might be used temporarily with propriety when something "should be done in a hurry," but after it has been done it would be in the interest of better English and pathology to employ a more elegant and accurate expression.

M. W. LYON, JR., South Bend, Ind.

[COMMENT:—Scientific medicine demands scientific phraseology. When a doctor "operates" his patient, let it be understood that he "works" him. And if he "operated on" him, let him say so. "Operated cases" and "The child had no temperature" are further samples of the loose English too often used by scientific men.—ED.]

PHYSICIANS AND GENETICS

To the Editor:—"Given an incorrect diagnosis and you can cure any disease" is, I believe, a current saying in the profession. It seems to draw attention to one of the most striking spectacles of modern times—the expanding field of knowledge which the physician is drawing on for his diagnosis. The day is gone by when a look at the tongue and a count of the pulse and a few words with the patient are enough. The modern physician has come to realize that his patient is more than the product of a few years of growth; that he is, in fact, a combination of human stocks with hereditary tendencies.

What diseases are coupled with the hereditary traits? Which are independent of them? How allay the unwarranted phantoms of "hereditary diseases" in nervous patients? How can we distinguish the hereditary tendencies from phenomena of nutrition? These have come to be real questions with every physician. In the field of heredity, as in few others, the evidences of the laws of inheritance are being

traced in widely different kinds of living creatures, and no physician can afford to overlook the great experimental work of the agricultural research men of America in this field. Their experiments in the breeding of plants and animals under conditions of control such as physicians cannot have, and on a scale which is impossible in the human species, are creating a fund of knowledge which the physician is bound to recognize.

Sixteen years ago, the secretary of agriculture established an association to bring together the breeders of plants, the breeders of animals, and those interested in human heredity. This association, now the American Genetic Association, has grown and become a real factor in the dissemination of the knowledge of heredity through the distribution to its members of a profusely illustrated journal—the *Journal of Heredity*—which is the property of the association. It is not a journal of the superficial class, but a serious one with contributions from specialists.

No longer should the confusion continue between what characteristics come to us in our inheritance and what ones are acquired. We must understand the importance of each, and not confuse them, if we would produce, by the only way possible, a better and nobler race of human beings.

The physician has become the father adviser of the race. It is in his hands, as in no others, to improve it by his advice and suggestion regarding the most vital problems that come to each individual. The science of genetics is already indebted to him for many great discoveries in eugenics, and from now on looks to him for many of the observations on which the generalizations of the future are to be made. No other class of people is more needed in the building of an American genetic association. May I ask your readers to send to the American Genetic Association, Washington, D. C., interesting photographs and accounts which illustrate the working of the laws of inheritance? A special illustrated folder, containing eighteen illustrations of heredity, will be sent to any one interested in this great subject.

DAVID FAIRCHILD, Washington, D. C.,
President, American Genetic Association.

MEDICAL VETERANS OF THE WORLD'S WAR

To the Editor:—Under this name, an organization was effected at the meeting of the American Medical Association in Atlantic City in June, 1919. At that time the membership numbered about 1,200. The executive committee held a meeting in St. Louis, October 15, and at that time the membership had increased to about 2,200. No profession responded more nobly to the country's call than did that of medicine. At least one third of all the legally qualified physicians in this country served in the Army, Navy, or on the Selective Draft Boards. All of these are eligible to this organization.

The purposes of the organization are multiple and varied. In the first place, it is hoped that annual meetings will give opportunity for renewing acquaintanceship begun and developed in camp and in field. It is desirable to preserve the memory of the hundreds of our profession who fell in defense of their country. Those who aided in making the world safe for democracy should be able to have some word in determining what kind of a democracy they fought for. It is not intended that this organization should be political in any sense, but it will be expected that it will be patriotic in every national and state problem that confronts us in the future. Provision is made in the constitution of this organization for state and local chapters. The membership should be extended until it includes all those that are eligible. The physician is interested in everything that touches the national welfare, and on many points in this connection he is the most competent man to speak. As individuals, medical men may have but little influence. Combined, the profession can be a tower of strength in everything that is good, wise and helpful.

THE LOS ANGELES MATERNITY SERVICE

A Municipal Dispensary*

LYLE G. MCNEILE, M.D.

Supervising Obstetrician, Los Angeles Health Department; Attending Obstetrician, Los Angeles County Hospital

LOS ANGELES

In many maternity dispensaries, the primary object has been the teaching of clinical obstetrics to medical students; in such instances the patient is regarded merely as "teaching material," and has been used principally in the teaching of diagnosis. Little attention has been paid to the normal case, and treatment has been detailed to poorly trained assistants. In many of these dispensaries, the actual delivery of the patient has been done by medical students without supervision, and little if any attempt has been made to follow up the case.

Other maternity dispensaries have been operated from purely charitable motives; and if the number of cases cared for by such dispensaries becomes large, the immediate needs of the patient are apt to be considered of paramount importance, and as soon as she is delivered her future is lost sight of.

It is only within recent years that the state has recognized that one of its duties in the promotion of public health is the maintenance and proper regulation of well equipped dispensaries. While health departments throughout the United States have in many instances maintained general dispensaries for the diagnosis and treatment of the common diseases, the obstetric work of the community has in general been left to private dispensaries, and to dispensaries maintained by medical schools and lying-in hospitals. With the

recognition of the economic value to the community of the unborn child, and of the child during the first year of its life, the public is becoming more interested in the problem of the maternity dispensaries. The public health dispensaries recognize the necessity for charity, and furnish, without charge to those who are in need, such medical services as they require. These dispensaries must also recognize, if they are to fulfil their entire function—the furtherance of every measure which would aid in maintaining the first degree of public health—that the proper education of medical students is a public health measure. It is well recognized that in the care of the pregnant woman an attendant possessing the highest type of medical education is required, if the mother and child are to be properly safeguarded. Public health is concerned not only with the life of mother and child, but also with the future health of both. It has been estimated that more than 20,000 women die each year in the United States of conditions which are the direct result of pregnancy. It would seem reasonable to argue that in the presence of such a death rate, health departments throughout this country should feel directly concerned with such measures as will materially reduce these appalling figures.

We feel that every woman has a right as a taxpayer—and all are taxpayers, either directly or indirectly—to demand such provision from the state as will insure her the best chance for a living baby, and good health following delivery.

With these various problems in mind, the Los Angeles Health Department in September, 1915, established the Los Angeles Maternity Service. The object of this service is to provide competent medical attendance for needy mothers, during pregnancy, labor, and the lying-in period.

GENERAL PLAN OF ORGANIZATION

The maternity service is actually the division of obstetrics, to which is referred anything of an obstetric nature which comes to the attention of the health department. In charge of this division is an assistant health commissioner, who is responsible only to the health commissioner.

The assistant health commissioner in charge of the division is known as the supervising obstetrician. The position can be filled only by a trained obstetrician, and not by a general practitioner. The supervising obstetrician receives his appointment from the health commissioner direct, and conditions in the Los Angeles Health Department are such that it seems probable that political activities will never determine the appointment of a physician to this position.

Two resident physicians report directly to the supervising obstetrician. These physicians are in reality interns in obstetrics. The senior resident physician receives \$75 a month, with room, and the junior resident physician receives \$25, and room. On appointment, the physician becomes junior resident physician, and after three months he is promoted to senior resident physician. The total length of service is six months, but the physician may elect to stay for a longer period. The resident physicians are appointed by the supervising obstetrician, and must be graduates of a medical college approved by the American Medical College Association, and licensed to practice medicine and surgery in California.

The assistant supervising obstetricians are appointed by the supervising obstetrician, and act as consultants to the resident physician on all cases. Their function is practically identical with that of the junior attending staff in hospital organization. The assistant obstetricians on this staff are all appointed as a result of teaching positions held by them in the obstetric department of either of the medical schools in Los Angeles.

The externs are senior medical students assigned in rotation from their respective schools for clinical work in

* Read before the Los Angeles Obstetrical Society (a section of the Los Angeles County Medical Association), May 13, 1919.

obstetrics. They serve continuously for two weeks on the dispensary staff, and report directly to the resident physician. They are at all times subject to, and under orders from, the supervising obstetrician and his assistants. All of their work is outlined and prescribed, and they are not allowed to do any obstetric work except under the direct supervision of the resident physician or a member of the staff. Conditions at present require the services of from three to five interns at all times.

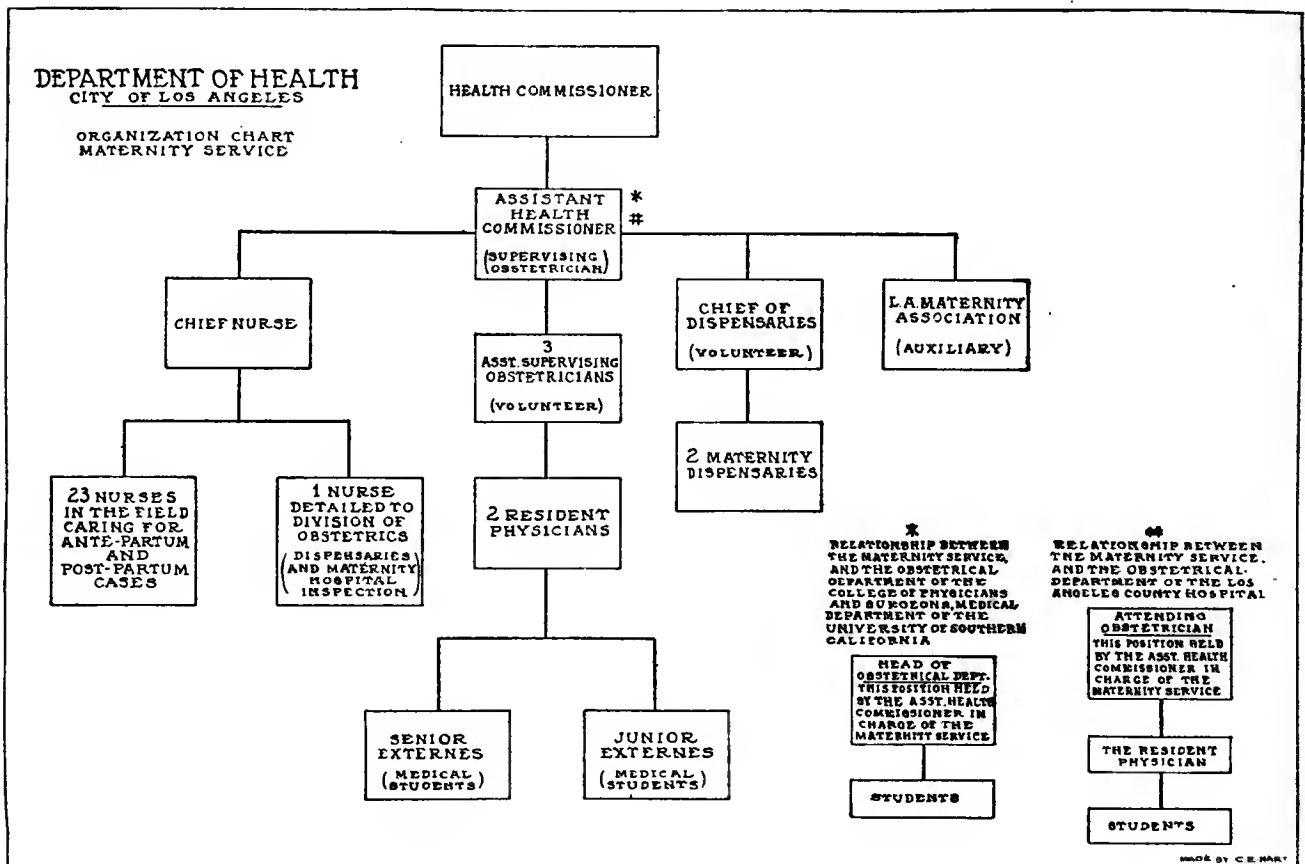

The nurses, twenty-four in number, receive their orders from the supervising obstetrician through the chief nurse in charge of the bureau of nursing. They are civil service employees. One nurse is assigned to maternity hospital inspection, attendance at maternity clinics, and the general work of this division. There are twenty-three nurses in the field who care for antepartum and postpartum cases. We do

maintains fifty beds for obstetric patients. In this hospital are provided adequate facilities for the care of such dispensary patients as require hospital care.

EQUIPMENT

The maternity service has been taken care of in the matter of quarters and equipment. Labor bags, each containing the necessary equipment for the conduct of a normal obstetric case, are provided for each extern. We have made it a rule to place no limit on the actual amount of sterile supplies used in a case, but each labor bag is supplied with a tin, sealed container, which contains a sufficient amount of sterile towels, pads, cotton pledgets, and cord dressing, with which to conduct the average case.

The resident physicians' bags are provided with the equipment found in the externs' bags, and in addition contain a

Organization of maternity service, Los Angeles department of health.

not, at the present time, receive the services of a nurse at the time of delivery.

RELATION TO ALLIED ORGANIZATIONS

It is, we believe, essential that in a dispensary service of this kind, the most intimate relationship should exist between the dispensary, one or more reputable medical colleges, and a first class hospital maintaining a department for the reception and care of obstetric patients. We believe that our plan of organization meets all of these requirements.

The supervising obstetrician also holds the chair of obstetrics at the University of Southern California Medical Department (College of Physicians and Surgeons). He is therefore in direct touch with a majority of medical students acting as externs on the service, and is able to appreciate the problems peculiar to the teaching of clinical obstetrics.

In addition, the supervising obstetrician acts as attending obstetrician to the Los Angeles County Hospital, which

Tycos sphygmomanometer, a perineorrhaphy set, forceps, and a copper sterilizer.

Each dispensary is provided with history desks, two gynecologic examining tables, two tables for external examinations, a sterilizing outfit, drug and supply cabinets, card index equipment, and the reagents and apparatus necessary for routine urinalysis.

Externs' quarters are provided at our Ninth Street Dispensary. Two rooms, each containing two beds, clothes closets, desks and bedside tables are sufficient at our Gless Street Station for the resident physicians.

A high pressure sterilizer is maintained at the Normal Hill Center for the sterilization of all supplies used on the service.

ROUTINE MODE OF PROCEDURE

Cases are reported to the office on a post-card form, report of maternity case, or by telephone in case of emergency. The majority of such reports come from district nurses,

charitable organizations, clinics, hospitals and other similar agencies. A relatively large number of calls come from new patients who have heard of the service from "old patients."

On receipt of a call, the clerk makes out a blank antepartum record, which is handed to the extern on duty. The extern sees the patient within a few hours, recording the medical and obstetric history, with the results of his obstetric examination. The patient is given a copy of our leaflet, "Advice to Those Who Are About to Become Mothers," and a dispensary card giving the location of the

§ All from influenza.

nearest dispensary, and directions for calling the maternity service at the time of labor. She is instructed to come to the maternity dispensary at least every two weeks throughout pregnancy, and to bring with her, at each visit, a specimen of urine for examination.

The routine procedure in caring for patients at the dispensary will be discussed under maternity dispensaries. If the patient cannot or will not go to the dispensary, an extern sees her at her home every two weeks throughout pregnancy.

Labor calls are handled by the telephone exchange maintained by the Los Angeles County Medical Association. On receipt of a call, the operator notifies an extern, who sees the patient immediately. As soon as the extern has made his external examination, he notifies the resident physician. The resident physician sees each patient during labor, and is present at each delivery.

All normal deliveries are cared for in the patient's home, but pathologic cases are, so far as possible, sent to the Los Angeles County Hospital, and remain on the service of our supervising obstetrician.

After the delivery, the bureau of nursing is notified, and a field nurse sees the patient each day for six days, and then on alternate days until the patient is discharged. An extern sees each patient once daily for five days, and then on alternate days until she is discharged. At each visit, routine medical and nursing care is given to the mother and child.

No patient is discharged for at least ten days, and then only if she presents no pathologic features. At the last visit, the extern instructs the patient to visit the dispensary in two weeks for final examination.

MATERNITY DISPENSARIES

At present, the maternity service is maintaining two dispensaries for the care of antepartum, postpartum, and gynecologic cases. In antepartum cases, the patients are carefully examined; external pelvic measurements and blood pressure are taken, and urinalysis is made at regular two week intervals. Internal measurements are taken only in early pregnancies.

We are able to make a postpartum examination of mother and child in nearly all of our cases. Gynecologic cases which

are not operative are treated in each dispensary, while operative cases are referred to the county hospital.

The effect of the educational work done in these dispensaries is becoming more and more apparent, as larger numbers of patients are coming in and asking that they receive antepartum care, as they have noticed that their friends who have received dispensary care get along better at the time of confinement.

The dispensaries care for a large number of women who expect to go to the hospital for confinement. The dispensaries are under the direct supervision of a trained physician, the resident physicians and externs acting as assistants. The physician in charge has always been a woman, and we are convinced that the best results in similar dispensary work can be obtained only by placing a woman physician in charge. It must be remembered that a majority of the maternity clinic patients are used to the attendance of one of their own sex.

SUPERVISION OF MEDICAL STUDENTS

During the first week of his service, the student is called the junior extern, and is expected to make from eight to twelve antepartum and postpartum calls each day, do the routine urinalysis, and attend the dispensaries. In his second, or senior extern week, he does all deliveries, subject to direct supervision, and attends dispensary.

From the time the student goes on duty, until he leaves, he is under the supervision of a member of the staff. He must report to the exchange every forty-five minutes, unless he is at the "quarters" or actually engaged in the delivery of a patient. In this way, we are able to handle the calls promptly, and to know at all times where the student is, and what he is doing. In addition, he is required to make a daily report in writing at the end of each day's work.

In order to avoid the frequent disagreements which so often follow the giving of verbal orders, a comprehensive outline of all the orders and technic used on the service has been issued in book form, and is given the student several weeks prior to his service.

The average extern makes from sixty to seventy calls in pregnant or postpartum cases, examines (externally) from

TABLE 2.—REPORT OF COST OF THE SERVICE

Year	1917	1918	1919
Equipment	38.50	35.90	293.39
Salaries	2,100.00	2,100.00	3,033.35

Supplies	251.22	419.67	622.28
Total	2,610.59	2,747.59	4,290.55
Cost per delivery	7.50	6.73	8.67
Cost per patient based on applications	4.93	4.35	5.55

thirty to fifty pregnant women in the dispensary, and delivers from eight to twelve women during his service. He is called to the county hospital to witness all pathologic cases occurring during this period.

RELATION TO CHILD WELFARE CENTERS

Every child delivered on this service is referred to the nearest child welfare conference for weekly weighing and supervision of diet during the first two years of its life. Through the cooperation of the district nurses, it has been possible to persuade a large majority of our patients to attend these conferences regularly, and a surprising reduction in first year mortality has resulted.

LOS ANGELES MATERNITY SERVICE ASSOCIATION

There has recently been organized an auxiliary association, formed for the purpose of aiding the maternity service. Through this agency more social service work will be per-

formed, increased facilities for dispensaries will be provided, and eventually a maternity hospital will be erected.

RECORDS

The necessity for accurate and systematic record keeping was recognized at the time this service was first formed, and an appropriate system was installed.

Each report of a maternity case is numbered and filed. A cross reference is made for surname and address in each case. The antepartum record is kept at the quarters and an entry of findings is made each time the patient is seen. All entries are checked by a member of the staff.

Labor records and postpartum records are made at the bedside, and the entries checked. On the completion of a case all the data are filed at the main office.

Daily reports are made by externs and resident physicians, and are made a matter of record. Semimonthly summaries are made on the first and fifteenth of each month, showing all details of the work performed during the current month. A general summary has been kept in such form that it is possible, with the use of an adding machine, to obtain the entire record of the service, or of any period since its establishment, within a few minutes.

CONCLUSIONS

We believe that the maternity dispensary can well be operated as a public health measure. Properly managed, it will aid in raising the standards in obstetric work; will supplant to a large extent the work done by midwives and substitute trained for untrained work; will decrease infant and child mortality; will provide for the registration of births, or other statistics which would otherwise remain unrecorded, and may, in many instances, provide more adequate facilities for the proper training of medical students in clinical obstetrics.

Book Notices

THE HEALTH OFFICER. By Frank Overton, A.M., M.D., D.P.H., Sanitary Supervisor, New York State Department of Health, and Willard J. Denno, A.B., M.D., D.P.H., Medical Director of the Standard Oil Company. Cloth. Price, \$4.50 net. Pp. 512, with 51 illustrations. Philadelphia: W. B. Saunders Company, 1919.

While it is seldom that a book is issued about which it can be said that it supplies a real need, the statement can be made of this book. So far as the United States is concerned the position of health officer is a new one. However, it is a position that already offers more opportunities than there are men to meet these opportunities. While he has the fundamental knowledge, the average physician is not qualified as a health officer unless he has especially prepared himself, for public health work is a specialty requiring as much special knowledge as any specialty in medicine. The book before us supplies this special knowledge. As the preface says, "It tells the health officer what to do, how to do it, and why he should do it. It describes the various activities in which a health officer engages; his relation to boards of health, physicians, social agencies, and the public; his qualifications and methods of work; the various diseases and insanitary conditions with which he deals; and the scientific principles on which the specialty of preventive medicine is founded." Actually, however, it does more; it discusses fully the more important contagious diseases from a public health point of view, giving diagnosis, management, methods of prevention, etc. The matter is up to date and reliable, the space allotted to the various diseases being wisely adapted to American needs. The illustrations are of practical value. As a whole the book is to be commended, not only to health officers but to all practitioners of medicine, for it contains information that should be available to every physician.

PSYCHOSES OF THE WAR, INCLUDING NEURASTHENIA AND SHELL SHOCK. By H. C. Marr, Lt-Col. R. A. M. C., Neurological Consultant to the Scottish Command. Cloth. Price, \$6. Pp. 292. New York: Oxford University Press, 1919.

This book purports to describe the results of the observation of some 18,000 officers and men; but in reality the author has attempted a textbook of psychiatry and has included descriptions of the various forms of low-grade feeble-mindedness. The text presents a curious mixture of abstracts, often poorly digested, from modern neuropsychiatric literature, with primitive conception which may well be termed popular. Thus, in the introductory chapter there is a detailed account of nerve structure followed by a description of the "means of observation of mental phenomena" in which there is little besides a study of facial expression, which is said to give "the most reliable information of the nature and quality of mind." Under the heading of psychasthenia the author quotes Janet (not quite correctly), and then proceeds to describe a series of cases of constitutional inferiority with delinquency which obviously bear no relation to the definition given. Hysteria is "neurasthenia of toxic origin." The system of classification is certainly original, but hardly more than illustrates the view of Dr. Marr that "the primary object of classification is to keep our thoughts in order, and this is difficult to effect in relation to insanity." The case histories are sketchy and incomplete in many particulars, diagnosis depends on a purely formal description of symptoms without analysis, and but little light is thrown on treatment. It is difficult to find any useful purpose that can be served by this book.

SEX AND SEX WORSHIP (PHALLIC WORSHIP): A SCIENTIFIC TREATISE ON SEX, ITS NATURE AND FUNCTION, AND ITS INFLUENCE ON ART, SCIENCE, ARCHITECTURE, AND RELIGION, WITH SPECIAL REFERENCE TO SEX WORSHIP AND SYMBOLISM. By O. A. Wall, M.D., Ph.G., Ph.M. Cloth. Price, \$7.50. Pp. 607, with 372 illustrations. St. Louis: C. V. Mosby Company, 1919.

This book is largely based on a collection of erotica available prior to 1896. It is a rather miscellaneous collection of material on the psychology of sex, mythologic beliefs, and the relation of sex to primitive religions. There seems to be a general lack of completeness on any single subject, and lack of organization is apparent not only in the individual chapters but also in the work as a whole. For these reasons the book cannot be classed as a contribution to the advance of knowledge on this subject, since it presents practically nothing that is not available elsewhere. It may, however, be of interest to the casual reader. The illustrations are in large part reproductions of old paintings and sculpture.

Social Medicine, Medical Economics and Miscellany

LIVING EXPENSES FOR THIRTY YEARS

There is probably no question today that the average American family views with so much anxious interest as the very practical one of the steadily advancing cost of living. Many discussions appear that take up the topic from various angles. One of the most unique contributions to the general subject appears in the *Outlook*, Dec. 3, 1919. The account given by R. R. R. of his household expenses for the thirty years period from 1889 to 1919 appeals to the reader more than government statistics, as it covers actual family experience and considers two of the elemental factors of human existence—income and outgo. The writer is the head of a family in Massachusetts, and has been a railway employee for thirty years. This significant record begins with 1889, the year of his marriage. In that year he introduced in the home the custom that each member of his family who bought an article was to write down the article and its cost on a tally board. Each week he entered these figures in his "house book." He found that his tally board system encouraged economy in his family. Entering everything on the tally board in black and white served to make the matter

of making ends meet a sort of game that everybody enjoyed. Would they meet or would they not meet? was always very much of a question. Some commodities, such as sugar and flour, were actually cheaper in 1899 than in 1889, and even up to 1909 there was not such a tremendous increase; the greatest came during the past ten, and more especially during the past four years. Table 1 well illustrates this.

TABLE 1.—A COMPARISON OF PRICES OF STAPLE COMMODITIES DURING A THIRTY YEAR PERIOD (1889-1919)

	Butter, per Lb.		Lard, per Lb.		Milk, per Qt.		Sugar, per Lb.		Flour, per Bbl.		Potatoes, per Bbl.		Coal, per Ton	
	Max.	Min.	Max.	Min.	Max.	Min.	Max.	Min.	Max.	Min.	Max.	Min.	Max.	Min.
1889..	\$0.34	\$0.26	\$0.10	\$0.09	\$0.05	\$0.05	\$0.07	\$0.07	\$7.50	\$6.50	\$0.80	\$0.80	\$6.00	\$6.00
1899..	0.34	0.25	0.10	0.08	0.06	0.05	0.05	0.05	5.00	4.50	1.00	0.75	6.75	6.75
1909..	0.34	0.26	0.16	0.12	0.06	0.06	0.06	0.05	7.00	6.25	1.20	0.75	7.50	7.50
1919..	0.80	0.58	0.43	0.32	0.15	0.15	0.11	0.10	14.00	13.00	4.00	1.00	12.05	12.05

Eggs have changed more than any other commodity. In 1897 the highest and lowest prices were 36 and 15 cents a dozen, respectively. In 1919 the maximum and minimum were \$1.20 and 40 cents. In 1894 and 1895 sugar was only 4 cents. The highest price prevailed in 1919.

It has been a very close race between the advancing prices and the writer's slowly increasing income. However, he has managed, with the aid of a \$500 legacy, to buy a home worth \$3,000 and to save \$1,600 besides. For life insurance about \$1,300 has been spent.

TABLE 2.—WAGE SCHEDULE DURING THIRTY YEAR PERIOD

Year	Daily Wage
1889.....	\$1.75
1892.....	2.30
1895.....	2.50
1899.....	2.75
1902.....	3.00
1907.....	3.25
1910.....	3.75
1916.....	4.00
1918.....	5.00
1919.....	5.50

Since 1903 the writer has been employed as a freight conductor on a small nonunionized railway. He concludes with the thought that while he and his family have never had much, they have had enough.

MODERN HYGIENE

Desfosses publishes in the *Presse médicale* a signed editorial with the heading, "Demagoras, hygieniste." He compares latros and Demagoras. Latros, the physician who has grown old helping the sick; his glory, the gratitude of a few whom he has saved from the tomb. Every day, every hour, he teaches practical hygiene. He is not afraid to tell Demos that many of his ills come from his bad habits; that physiologic poverty comes often from vices; that the best way to keep well is to be clean physically and morally; he tells the young men that the surest way to avoid venereal diseases is to keep from exposing oneself to contagion; he hints to the workman that cirrhosis and dropsy and even tuberculosis are picked up in the barroom (*se prennent sur le zinc*), and that accidents are often the consequence of imprudence or drunkenness. He teaches that progress in hygiene is possible only by individual effort. General measures are effectual only with the active collaboration of the individual. Every man hews out his own destiny. He preaches constantly moderation in eating and in pleasures, and regularity in habits. But Demagoras with his new diploma as hygienist, obtained after a few months in a bacteriologic laboratory and attending a few lectures on hygiene, declares that the sick are the victims of Society; that diseases are the result of the bad organization of public hygiene. If people are tuberculous, that is because the declaration of tuberculosis has not been made compulsory: how can a disease be combated if its exact prevalence is not

known? Far from exhorting Demos to lead a more hygienic life, his axiom is that Society is to blame for everything. If the laboring man drinks liquor, it is because he wants to forget; if he is lazy, it is because he does not get enough food. The young man should be able to obey without restraint the desires which Nature has implanted in him. It is for the antivenereal dispensary to render Venus safe and dry Cupid's tears. To establish once for all and absolutely school hygiene, urban hygiene, industrial hygiene, all that is necessary is to have numerous inspectors, well paid. Demagoras speaks with superb disdain of clinicians. He, himself, represents Science. Medicine for the physicians; hygiene for the hygienists. Demos can without fear seek his pleasures; Demagoras will assure him the scientific organization of hygiene. The people thus hear two voices preaching to them: To keep well, develop your individual energy, do not count on any one but yourself, says the physician. To keep well, develop the system of public functionaries, count on me, clamors Demagoras. We may well imagine how puzzling these two tendencies must prove to laymen accustomed to guide themselves by authority, and who under the circumstances cannot determine by themselves which is the correct advice. It would seem, however, that here as elsewhere, the middle of the road would be the safest, and that both individual hygiene and public sanitation must be observed if Society is to secure a maximum of protection against disease.

Medicolegal

Annulment of Marriage for Concealing Tuberculosis

(*Davis v. Davis* (N. J.), 106 Atl. R. 644)

The Court of Chancery of New Jersey holds that a court of equity has inherent jurisdiction, independent of statute, to annul a marriage on the ground of fraud; and that the suppression by one party of the fact that he is suffering from a disease which renders the close intimacy of the marriage relation dangerous, and which may result in a transmittal of the disease to offspring, is such fraud as will warrant a court of equity in annulling a marriage. More particularly, the court holds that where, at the time of marriage, the defendant husband was suffering from hereditary chronic tuberculosis, and did not inform the petitioner of the fact for the reason that he feared, if he did, she would not marry him, and it appeared that if she had been so informed she would not have, in fact, married him, there was such fraud as would warrant the court in annulling the marriage, notwithstanding the fact that the parties lived together as husband and wife for a period of six months, until the discovery by the wife of the existence of the disease, and notwithstanding the fact that there was a child born, which lived for only four days, where it appeared that, immediately on the discovery of the existence of the disease, the petitioner ceased cohabitation; and such being this case, a decree for the petitioner is advised.

It is well known, says Vice Chancellor Lane in the opinion in the case, that close contact with one suffering from tuberculosis involves great danger of transmission both through infection and through contagion. It is almost impossible to conceive the ordinary relationship of husband and wife existing without that danger ever present. There is always also great danger of transmittal of the disease to offspring, and, if the disease itself is not transmitted, there are likely to be transmitted characteristics which predispose toward the development of the disease. False representations with respect to its existence go, then, to an essential of the marriage relation. They are very different from representations with respect to health in general. They are more akin to representations of freedom from leprosy or diseases of similar nature. I cannot agree that the only diseases which affect an essential of the marriage relation are those of a venereal nature. I can see nothing whatever in good policy, sound morality, or the peculiar nature of the marriage

relation which would warrant the court, after having found the fraud, denying relief. Neither good morals nor public policy are subserved by compelling parties to live together as man and wife, with the ever-present danger of infection, and beget offspring liable to be tuberculously inclined, nor are they subserved by compelling a woman, who has married under a misrepresentation with respect to the fact, to continue to be bound to a man affected with tuberculosis without having the close intimacy to which she is entitled. I am unable to conclude that there is any essential difference, so far as the matter now under consideration is concerned, between tuberculosis and syphilis.

While due caution may require a party to a marriage contract to make his own investigation with respect to fortune, family and other external conditions, it seems to me to be going too far to say that due caution requires a party to a marriage contract to require the production of a medical certificate, and in the case at bar a medical examination would have been required to advise the petitioner of the condition of the defendant. Such a rule is not applied in the case of syphilis, nor do I think it should be in the case of tuberculosis. The suppression by the defendant of the fact that he was suffering from tuberculosis of the nature that he was, for the reason that he did suppress it, was equivalent in law to an express representation on his part that he was free from it.

Board of Health Refusing Permit for Hospital

(*People ex rel. Sprenger v. Department of Health of City of New York* (N. Y.), 123 N. E. R. 379)

The Court of Appeals of New York, in affirming an order of the appellate division that affirmed one granting a peremptory writ of mandamus commanding the defendant to grant the relator a permit for a private hospital for the treatment of medical, surgical and obstetric cases, says that the head of the department of health of the city of New York is the board of health. The sanitary code enacted by the board of health provides that no person shall conduct a private hospital without a permit therefor issued by the board of health. The regulations of the department of health provide that the proposed site and sanitary condition of the hospital building shall be subject to the approval of the department of health. The charter of the city provides that the board of health may embrace in the sanitary code all matters and subjects to which, and so far as, the power and authority of the department of health extends, not limiting their application to the subject of health only.

The board has general jurisdiction over the establishment and maintenance of hospitals, including the licensing of hospitals. On an application for a permit, it should consider and give proper weight to all the ordinary contingencies and circumstances appropriate to the subject which require the exercise of discretion. The element of location may be material. The effect of a proposed location on property values in the neighborhood need not be wholly disregarded, and may even become decisive in a case otherwise doubtful. But the authority now conferred on the board does not include, expressly or by reasonable implication, the power to refuse a permit, as was done in this case, when all other conditions are satisfactory and no offense to the senses is suggested, for the exclusive reason that "considerable damage would accrue to the surrounding property if the permit were granted." That reason considered alone came not legally within the scope of its discretion. The property rights of one owner may not be subordinated to the property rights of his neighbors, except as an incident to the exercise of authority reasonably conferred for the general welfare. The action of the board was, as the law now exists, unauthorized, and therefore unreasonable and arbitrary; the relator's remedy was mandamus; and the order appealed from should be affirmed, with costs.

The question of legislative power wholly to exclude hospitals, such as hospitals for contagious diseases or for the treatment of inebriates or the insane, from particular places, such as thickly populated or fine residential districts, was not before the court.

Inadequate Ordinance and Complaint of Board of Health

Board of Health of City of Paterson v. Clayton et al. (N. J.), 106 Atl. R. 813

The Supreme Court of New Jersey, in affirming an order setting aside a conviction of defendant Clayton of a violation of the health code of the city of Paterson, says that the section of the code, or ordinance of the board of health of the city, which he was charged with violating, reads:

"That whatever is dangerous to human life or health, whatever building, erection, or part or cellar thereof is not provided with adequate means of ingress and egress or is not sufficiently supported, ventilated, sewerage, drained, cleaned or lighted, and whatever renders the air, food or water unwholesome, are declared to be nuisances and are prohibited. Any person violating any of the provisions of this section shall be liable to a penalty of not less than five dollars nor more than one hundred dollars."

The complaint charged that Clayton violated the provisions of this section in this, that he "had people congregated and invited people to congregate in his saloon," at a certain location, such action of his "being dangerous to human life and health, there being an epidemic of influenza in the city." But the court does not think that the complaint charged any violation of the section. Passing the argument, which had much to support it, that the ordinance was aimed at physical conditions pertaining to inanimate objects, and not at human conduct, and, conceding for present purposes that the assembling of a numerous crowd in an unventilated and confined room during an epidemic of contagious disease was within the purview of the ordinance, as to which the court expresses no opinion, there was yet no allegation of any such act in the complaint. Certainly the mere inviting people to congregate in the saloon was not dangerous to life or health. As to the charge of "having people congregated" in the saloon, it might have been as few as three, and there was no proof that there were more, came together at the instance of Clayton in a saloon, of unknown dimensions, with unknown facilities of ventilation; on a certain date, while influenza was in a general way epidemic in the city. It may be freely conceded that epidemics of contagious and infectious disease may be, and have been, so severe and dangerous as to justify the most drastic rules against personal contact of individuals, but there was nothing in the complaint to show that such conditions prevailed in this case, and if they did prevail, the ordinance was not such a rule as to meet the emergency, and it did not support the complaint, which under well-recognized rules must be taken at the minimum of the facts charged.

Physicians Not Required to Report to Defendants

(*Tutone v. New York Consolidated R. Co.* (N. Y.), 177 N. Y. Supp. 818; *Herbert v. Brooklyn Heights R. Co.* (N. Y.), 177 N. Y. Supp. 901)

The Kings County, N. Y., court holds in these two personal injury cases that orders for the physical examination of the plaintiffs by physicians were erroneous in requiring that the reports of the physicians should be given to counsel for the defendants. The decisions are by two different justices. In the Herbert case, Justice May says there is nothing in the New York statutes which directs or requires a report to be made by the examining physician. The sole object of the statute in permitting physical examinations is to reduce the likelihood of fraud being practiced to a minimum, by granting the right to the defendant to compel the plaintiff merely to submit to such physical examination at the hands of the physicians, so that testimony thereof may be given on the trial. While it has been customary for physicians so appointed to make a report and deliver it to the defendant, there is no authority apparently in the law therefor. There may be no objection, perhaps, to the disclosure by the physician to the defendant of the results of his examination, but the court has no power to direct him to make such report, and therefore it follows that there can be no direction to deliver a report to the defendant, or to file a report in the office of the county clerk.

- *Résumé of Experimental Studies on Cutaneous Hypersensitiveness. E. C. Fleischner, K. F. Meyer and E. B. Shaw, San Francisco.—p. 577.

Hydrocephalus in Meningitis.—Blackfan carried out the phenolsulphonaphthalein test in twenty-five cases of meningitis in which hydrocephalus had developed, and had roentgenograms made after the injection of the ventricles with air. Seventeen cases were caused by the meningococcus. Communicating hydrocephalus developed in eight of these cases, and the obstructive form in nine. Ten of the seventeen patients died. Two of the seven patients who recovered had an obstructive hydrocephalus and improvement followed promptly after the introduction of antimeningococcus serum into the ventricles. In four cases in which a communicating hydrocephalus was present, the process became arrested after treatment. The patients made an uneventful recovery. One patient developed a chronic hydrocephalus (communicating). A ventriculogram showed almost complete destruction of the cortex. A necropsy was performed in the ten fatal cases, and the clinical diagnosis was confirmed by demonstration of the exciting cause of the hydrocephalus. In seven cases of obstructive hydrocephalus an exudate occluded the foramina at the base of the brain, and in three cases of communicating hydrocephalus the basal cisternae were totally obliterated by a thick purulent exudate.

Antineuritic Vitamin.—The investigation reported on by Daniels, Byfield and Loughlin indicated that the addition of the antineuritic vitamin obtained from wheat embryo to the diet of babies who are supplied with food furnishing an adequate number of calories stimulated growth. The beneficial influence of adding a specially prepared vegetable soup in sufficient quantity as a part diluent in the milk modifications for infants is apparently due to the presence of the antineuritic vitamin contained therein. Both the alcoholic soluble material of the dried soup vegetables, and the water extract (soup) stimulated growth. The fact that the artificially fed infant requires a larger amount of food than the breast fed infant appears to be due to the relative paucity of diluted cow's milk in the antineuritic vitamin. The authors suggest the probability that failure of infants and young children to gain is often the result of an insufficient amount of the antineuritic vitamin in the food, therefore, the diets of the young should be scrutinized more carefully with this in mind.

Blood Chemistry.—Chemical blood observations were made by Chapin and Myers on 149 children, thirty-eight of whom were nephritics and six diabetics. In general, the results obtained are quite similar to those obtained in the adult, although the kidney of the child would appear to act somewhat more efficiently than in the adult, resulting in slightly lower normal figures for the sugar, urea, creatinin and uric acid, and a slightly better phenolsulphonaphthalein output. In harmony with this, nephritis in children does not so quickly result in urea retention as in the adult, making the prognosis more favorable in early than in later life. As might be expected, creatinin retention rarely occurs in children. The authors regard the blood urea as an especially helpful prognostic test in the nephritis occurring in children. The results of phenolsulphonaphthalein tests harmonize very well with the clinical findings and the blood urea. The carbon dioxid combining power of the blood is a very real-

able method of ascertaining the severity of the acidosis in the diarrheal acidoses. The blood findings of diabetic children do not differ from similar observations in adults.

Cutaneous Hypersensitiveness.—Fleischner and his associates found that bacterial proteins, soluble or insoluble, which sensitize a guinea-pig in an anaphylactic sense will not sensitize its skin.

Recent Advances in Gastric Physiology.—Evidence is presented by Alvarez which suggests strongly that there is a gradient of metabolism underlying and, perhaps, giving rise to the gradients of irritability, latent period and rhythmicity which, it is believed, determine the direction of peristalsis. The metabolic gradient is often found reversed in such animals which are refusing food. There appears also to be a gradient of metabolism in the mucous membrane of the stomach. The lowest values in the whole digestive tract are found in the antrum. It is shown how this may explain the high incidence of cancer in that region and the inability of the tumors to cross over into the duodenum, where there is a very high metabolic rate. An explanation is given for the fact that a sleeve resection gives a better functional result in ulcer of the lesser curvature than a V excision.

Persistent Eosinophilia.—Giffin's patient was a man, 31 years of age. He had a marked splenomegaly, slight enlargement of superficial lymph glands; leukocytosis—21,800 before splenectomy—with an eosinophilia of 73.6 per cent. The spleen was removed. It weighed 2,110 gm. Macroscopic appearance was similar to that of the spleen in myelogenous leukemia. The leukocyte count rose rapidly to 97,200 and later to 211,000; eosinophilia rose from 79 to 90.7 per cent. The patient was in good general condition for a period of four years following splenectomy. Death was due to empyema following pneumonia. At the necropsy, enormous numbers of eosinophilic polymorphonuclears were found in all hemopoietic organs; eosinophilic myelocytes were numerous in lymph glands, spleen and bone marrow. Giffin regards the case as an instance of eosinophilic hyperleukocytosis, the blood picture of which was remarkably altered by splenectomy, and suggests a special function of the spleen with respect to eosinophilic cells or with respect to the toxins which eosinophilic cells are capable of absorbing.

Heart in Bronchopneumonia.—In the cases studied by Hart the routine method adopted was to begin the administration of digitalis as soon as the diagnosis of pneumonia was reasonably sure. There was given of the tincture 25 minims, every four hours, for six doses, which was then reduced to 15 minims, every eight hours, and continued, with modification according to the individual indications, throughout the course of the disease. Patients who developed symptoms of toxemia very rapidly or who were found in this condition on admission, were frequently given from 15 to 30 minims of a digitalis preparation intravenously, and this was repeated every four hours, up to three or four doses, after which time the tincture was usually substituted. For the sake of com-

parison and control a considerable number of cases were from time to time selected at random and treated by methods identical in all respects, except that in these no digitalis was administered. Absolutely no difference in the course of the disease could be observed in the two series, except that the electrocardiograms of those patients receiving digitalis showed the characteristic changes, and in two instances an arrhythmia developed which proved to be due to a condition of partial heart block. The patients to whom digitalis was given ran their course without a change in the pulse rate which could be attributed to the drug. The terminal increase in the heart rate in the fatal cases was identical in both groups. No difference could be noted in the two series in the behavior of the blood pressure. In two cases of chronic cardiovascular disease with auricular fibrillation, the circulatory condition was much improved, the heart became slow and appeared reasonably efficient. Four patients out of several hundred to whom digitalis was given, showed block following digitalis, but recovered and gave no evidence of subsequent ill effects from its administration. In one case block appeared only after the administration of 465 minims of the tincture, in another an almost identical cardiac activity appeared after the administration of 230 minims of the tincture. Other patients in the series received considerably larger amounts of digitalis, and yet showed no evidence of heart block.

Transfusion of Blood in Pernicious Anemia.—Following two injections of 500 c.c. of whole blood (ten months apart), Anders' patient was so much improved in every way that he was able to attend to duties that he had not performed for the past ten years. Anders reviews the literature of 362 cases in which the result was given; in 204, or 56.3 per cent., there was an initiation of remissions. The average number of transfusions per patient was 2.4.

Hypertension Arteriosclerosis and Nephritis.—In many instances, at least, Moschowitz says the pathologic changes in the kidney of Bright's disease are the results rather than the cause of hypertension. Such a conception would render it very probable that the hypothesis of the primary vascular origin of the lesions in the kidney in Bright's disease is correct. Arteriosclerosis and Bright's disease have therefore the same pathogenesis, the lesion in each being modified by the nature of the organ. The direct etiology of hypertension is unknown. However, a type of person is described, conforming to certain physical and psychic complexes, in whom hypertension is very likely to occur. This type is the antithesis of the child, both in mind and spirit.

Meningo-Encephalitis Due to Mumps.—The three cases reported by Howard are regarded as instances of mumps meningo-encephalitis, in spite of the absence of inflammation of the salivary glands, for the following reasons: 1. They occurred in the presence of a mumps epidemic. 2. Two of the patients had never had mumps, while the third had been told by his father that he had had mumps, but could not remember it himself. 3. They all presented mild symptoms of meningo-encephalitis, which were entirely relieved or much ameliorated by spinal puncture. 4. In two of the three cases there was recovered from the spinal fluid a gram-positive diplococcus. This was found in direct smear and grown in pure culture in both cases. In the third case it was found in smear three times and recovered in culture twice. 5. The spinal fluid in each case presented a moderate pleocytosis, characterized by a predominance of mononuclear cells. The conditions which show this picture are (a) syphilis, (b) sometimes tuberculous meningitis, (c) encephalitis lethargica and (d) mumps. As to syphilis, two of the patients were negative serologically and the third, while having a positive Wassermann, repeatedly showed the presence of a gram-positive coccus in the spinal fluid. Tuberculous meningitis is ruled out in all cases by the clinical course. The same is true of lethargic encephalitis, there being no cranial nerve involvement and no palsies of any kind. There was also lacking the increase of tendon jerk almost uniformly present in this disease.

Heart Myxoma Simulating Bronchopneumonia.—Norton describes the clinical and necropsy findings in his case in

the hope that eventually a symptom complex for cardiac tumors may be worked out. The left auricle was filled by a tumor mass which was implanted by a broad base on the auricular wall. It was made irregular by polypoid-like growths, bulging the fossa ovalis into the right pulmonary vein, another into the mitral orifice and so completely filling the cavity that it was difficult to pass a small flexible probe between the tumor and auricular wall into the left ventricle.

Bacteriology of Mumps.—Five cases of mumps are reported by Haden in which a gram-positive diplococcus was isolated from the spinal fluid, the blood and a lymph gland. The injection of the organism into the testicle of a rabbit produced a severe orchitis in ten days. These findings confirm previous reports.

Vaccination by Subcutaneous Injection.—A similar article was published in the *Lancet* 2:285 (Aug. 16) 1919, and abstracted in *THE JOURNAL*, Sept. 20, 1919, p. 942.

Laboratory Studies in Influenza.—The epidemic of influenza at Camp Travis was characterized by the presence of the bacillus of Pfeiffer in 39 per cent. out of a total of 868 throat cultures examined. Blood cultures in the influenza cases were all negative. Blood cultures in the complicating bronchopneumonias gave 11 per cent. positives. The organism recovered was the pneumococcus. The blood picture of the average case of influenza showed a slight leukopenia, with a relative increase of the small mononuclears. When the bronchopneumonia developed there followed a slight increase in the total leukocyte count and an increase of the polymorphonuclears. Chemical examination of the blood showed a retention of urea nitrogen in the pneumonias having no kidney involvement. The retention of urea nitrogen in cases with transient nephritis was no greater. It is Matz' opinion that this retention in the bronchopneumonia under discussion was due to protein injury and disintegration, associated with extensive lung inflammation. Blood chemistry in the empyema cases showed a retention of urea nitrogen. Acidosis was a factor in a large number of the bronchopneumonias.

Treatment of Sarcoma of Long Bones.—This paper consists chiefly of a report of the cases of sarcoma of the long bones that have come under Coley's personal observation during the past five years, with a brief review of cases previously published. The toxin treatment was resorted to in these cases.

Postoperative Suppurative Parotitis.—Fisher claims that septic parotitis is of hematogenous origin, and that cachexia and malnutrition, by lowering resistance, are predisposing factors. The secretion of the gland is under the influence of nerve stimuli, and the incidence of postoperative parotid involvement is neurologically dependent on surgical shock or inhibition of the secretory and trophic fibers from higher psychic centers. The gland must be susceptible to pyogenic micro-organisms, and when affected, bacteriemia exists in all cases. Early incision and drainage are indicated.

Experimental Study of Buried Bone.—The conclusions reached by Ely in former studies are confirmed, but this series indicates, in addition, that the bone and marrow of the buried fragment both die. The marrow is then reformed by blood vessels, pushing in from the surrounding tissues, and a certain amount of new bone is laid down on the old, especially along the margins of the trabeculae. The cartilage usually lives, but slowly becomes eroded at its surface, and becomes thinner. Its buttress soon disappears. Raw bone resists absorption better than boiled bone, but it also is slowly absorbed.

Transmission of Influenza.—The results of all human experiments with the Pfeiffer bacillus, with secretions, with direct exposure, with subcutaneous inoculation of filtered secretions and unfiltered blood, were entirely negative in the work reported on by Leake. Micrococci of the group found by Mathers as very frequent in the respiratory tract of influenza patients were similarly inoculated without result. A sudden outbreak of 215 cases of influenza furnished donors for other experiments which also were negative. Two men, however, developed acute follicular tonsillitis, and a strongly hemolytic streptococcus became the predominating organism in the throat. In one of these patients the symptoms resembled influenza nine hours after onset. Transfer was then made of his secretions to ten more volunteers. In all of these ten, with one exception, the strongly hemolytic streptococcus became the predominating colony, and five of the nine developed acute follicular tonsillitis about two days after inoculation. This other volunteer, five days after inoculation, suddenly began to have a headache, fever, prostration and cough, pains in the back, etc. At first his nasopharyngeal bacterial flora were not much altered but after several days of sickness, Pfeiffer's bacillus began to be the predominant organism. The donor from whom the patient was inoculated apparently had an acute follicular tonsillitis due to the hemolytic streptococcus (beta type) though he had in turn received secretions from true cases of influenza. Another set of ten volunteers received the secretions obtained from an uncomplicated case of influenza four hours after onset. All of these remained well except one, who after thirty-six hours began to have fever, pain

in the back and chest, cough, anorexia, etc. The same bacteria were present after as before inoculation, but instead of the hemolytic streptococcus being predominant as at first, its place was taken by the Pfeiffer bacillus, which was second in importance before inoculation. Fifty-four hours after onset, an attempt was made to transfer the infection by means of secretions to the final group of fifteen volunteers, but without success. It appears from these experiments that influenza is transmissible by means of the nose and throat secretions of persons suffering from the disease, with the nose and mouth as portals of entry, but that such transmission is far from a uniform result of such exposure; the first twenty-four hours of the disease were the most favorable for this transmission. The customary measures for prevention are therefore reasonable.

Effect of Hemorrhage on Alkaline Reserve.—The blood examined by Buell was obtained without anesthesia from a spurting artery so that it only came in contact with the flask in which it was collected. When the animal remained perfectly quiet throughout the experiment, the drop in alkaline reserve was invariably small. If the animal struggled, the drop in alkaline reserve was much greater, this being noticeable soon after struggling took place. When the animal remained quiet, the maximum drop in alkaline reserve was reached within half an hour after the bleeding was completed. At the end of five hours, and often sooner, the alkaline reserve was near its original value. The total nitrogen content of the blood always fell immediately after hemorrhage. There was a distinct tendency for the urea nitrogen and the nonprotein nitrogen to rise. Although one animal was bled seven times while restricted to a diet of corn and water, the percentage of chlorids in the blood remained constant. On an inadequate diet (corn and water) under conditions of repeated hemorrhage there was a distinct tendency toward regeneration of blood proteins.

Effect of Hemorrhage on Nitrogen Metabolism.—The theory that hemorrhages amounting to 6 c.c. per pound of body weight are not necessarily accompanied by a severe grade of acidosis is supported by Buell's observations.

Antiscorbutic Value of Banana.—The value of the banana as an antiscorbutic in the treatment of experimental scurvy was investigated by Lewis. Guinea-pigs fed on an exclusive diet of bananas were unable to maintain their body weight and died in from twenty to thirty days. Bananas in amounts greater than 25 gm. daily, as supplement to a diet of rolled oats, prevented the onset of scurvy. Such a diet, however, does not protect against scurvy. These experiments suggest that a lower content of the antiscorbutic principle may be sufficient to protect against scurvy if the diet is adequate in its content of the other essential dietary constituents.

Determination of Carbon Monoxid in Blood.—Van Slyke and Salvesen have worked out a gasometric method which permits the determination of the carbon monoxid gasometrically in 2 c.c. of blood in the course of from ten to fifteen minutes. The technic is exactly the same as that previously described by Van Slyke for the determination of oxygen, except that after the gases are extracted the oxygen is absorbed in the apparatus by introducing alkaline pyrogallate solution. The carbon monoxid remains and is measured directly at atmospheric pressure.

Heat Coagulation of Milk.—Sommer and Hart found that the main factor in the heat coagulation of fresh milk is the composition of the milk salts. Apparently, casein requires a definite optimum calcium content for its maximum stability. The calcium content of casein is largely controlled by the magnesium, the citrates and the phosphates present. In fresh milk there is no relation between titratable acidity and heat coagulation. Acid fermentation in milk lowers the coagulating point by changing the reaction and by lowering the citric acid content. However, the titratable acidity of fresh milk samples varies so widely that it is impossible to determine the extent of acid fermentation by titration. Therefore, it is impossible to use the acidity of milk as a criterion of coagulability. Difference in concentration accounts partly for the difference in coagulation of fresh milk samples. Hydrogen ion concentration is not the determining factor in fresh milk coagulation. It is, nevertheless, a factor in fresh milks, and in commercial milks it may become an important factor.

Use of Pancreas Emulsions in Experimental Diabetes.—Diabetic dogs were given intravenous injections of unfiltered water extracts of fresh pancreas, diluted with 0.9 per cent. sodium chlorid solution. The preparation was administered very slowly and usually resulted in a marked decrease in the blood sugar. There was no compensating increase in urinary sugar, but rather a decrease, which may be owing partly to a temporary toxic renal effect. The result is regarded by Kleiner as further evidence for the internal secretion theory of experimental diabetes. The fact that these pancreas emulsions lower blood sugar in experimental diabetes without causing marked toxic effects indicates a possible therapeutic application to human beings, but further study of the problem is necessary.

Creatinuria in Infants.—The subjects of the experiments described by Gamble and Goldschmidt were infants obtained from a well conducted home for foundlings. One of them was a normal infant. The others failed to come up to the specifications for normal infants only in the respect that they were more or less underweight. There was in no instance a history of recent nutritional disturbance, or during the experimental periods, symptoms of malnutrition. They all made moderate or rapid gains in weight on the experimental diets. The diet was in all cases cow's milk. The results obtained show: first, that in the infant small amounts of ingested creatin lead to an increased urinary output; second, there is evidence that in infants the ingested creatin in nearly or completely eliminated during a period of several days. Third, from a comparison with experiments in the literature of the behavior of creatin ingested by adult men with the behavior in the infants studied, the following points are suggested: (a) smaller absolute amounts of ingested

creatin lead to urinary excretion of creatin in infants than is the case with adult males: (b) ingested creatin is more completely excreted by the infant than by the adult male; (c) although the comparison presents greater difficulties of demonstration, there is an indication that, per kilogram of body weight, smaller quantities of ingested creatin lead to excretion of creatin in infants than in adult males.

Id.—On the assumption that preformed creatin in milk modifications is in proportion to the quantity of whey present, the results reported by Gamble and Goldschmidt suggest that the ingestion of creatin is probably a large factor in the creatinuria of infants fed on cow's milk.

Otolith Organs and Semicircular Canals.—The results of experiments have convinced Maxwell that the assumption of a sharp differentiation of function between the otolith bearing vestibular portions of the labyrinth and the semicircular canals is not justified by the facts. Between the effects of extirpation of the one and of the other set of structures there is more resemblance than contrast. They certainly reinforce each other, for the reactions produced by either one alone are always slower and less vigorous than when both sets of organs are intact. It would not, however, be safe to affirm that the functions are identical. In one respect a difference is apparent; namely, in the response to rotation in a horizontal plane. If the ampullae are uninjured, compensatory movements occur when the animal is rotated around its dorsoventral axis. Maxwell has never seen this reaction in the absence of the ampullae of the horizontal canals.

Iodin and the Thyroid.—Swingle holds the view that iodine will eventually take rank along with chlorine, phosphorus and other elements essential to the maintenance of normal metabolism, growth, and development. The almost universal occurrence of a thyroid mechanism among the vertebrates for the assimilation and utilization of iodine in minute quantities, points to the conclusion that there is a definite iodine metabolism and that it is necessary for normal functioning.

Studies on Irritable Heart.—The authors prefer the name "irritable heart" to "effort syndrome." Many diseases and convalescence from many other diseases reveal practically the identical syndrome. However, the cases of true irritable heart have one factor not usually found in other cases showing a similar syndrome, that is history dating back years with no definite cause. The victims at times seem to be born with a constitutional inferiority. The least touch of the throttle races the engine. They seem unable to get into gear and carry the load. Exercise under observation is unquestionably the surest and quickest method of sorting the fit from the unfit. Graded exercise is also valuable in diagnosis between cases of irritable heart and pulmonary tuberculosis.

Nonspecific Protein Therapy.—Boyd has resorted to this form of therapy, using typhoid bacilli, in cases in which there is a chronic intoxication from some focus of infection which cannot be located or removed. The toxins may give rise to arthritis, myositis, neuritis, or iritis, depending on the organ whose resistance is below normal, but if the focus can be attached and the toxins neutralized, benefit will follow. In several cases of toxic iritis, infective arthritis and neuroretinitis, favorable results were obtained.

Incidence of Syphilis Among White and Colored Troops.—Based on the ++ reactions alone, Levin found 10.5 per cent. syphilis among the white and 18.3 per cent. among the colored soldiers. Considering the + reactions in this series also diagnostic, the percentage of syphilitics was 13.08 for the white and 24.1 for the colored soldiers. Estimate is made that the same and probably a higher percentage of syphilis exists among the white and colored civilians from 21 to 31 years of age.

Sphincter at Duodenal End of Common Bile Duct.—The tone of the sphincter at the duodenal end of the common bile duct was studied by Mann in species of animals possessing a gallbladder and in two species in which the gallbladder is lacking. It was found that the tone of the sphincter under the experimental conditions studied varied considerably in the different animals and various species. In each species possessing a gallbladder, however, the sphincter was usually able to withstand a minimum pressure of from 75 to 100 mm. water. In the species lacking a gallbladder, the sphincter would not withstand pressure, or only pressures of less than 30 mm. water. While anatomic studies have shown that a sphincter is present in each species lacking a gallbladder, the sphincter does not seem to functionate appreciably.

*Round Cell Sarcoma of Arm. J. G. Montgomery, Kansas City.—p. 421.

Intestinal Obstruction.—This paper was abstracted in THE JOURNAL, June 28, 1919, p. 1930.

Treatment of Influenza in Children.—In the treatment of influenza in children, Zahorsky favors sodium benzoate, and, as there is a marked tendency to acidosis, he adds potassium citrate, about 4 grains of each drug per dose every two hours. As a rule, quinin was prescribed in the severe cases and seemed to be of service in lowering the temperature. Intramuscular injections of quinin were used in two cases. For the distressing cough, paregoric or codein were occasionally prescribed. In all children showing considerable prostration camphor was used as a stimulant. It was generally prescribed in the form of spirits of camphor, and from 5 to 15 drops diluted with milk were administered several times a day. In a few cases the neutral camphor in oil was given hypodermically. Coffee and tea also were frequently used as stimulants. In one serious case of pneumonia, the principal stimulant was caffeine, given hypodermically. The treatment in these cases was guided by the theory that the child had to produce certain antibodies. For this purpose it needed rest, fresh air, food and light. Zahorsky did not use vaccines.

Round Cell Sarcoma of Arm.—In Montgomery's case several points are emphasized: (1) the sarcoma of the humerus apparently developed after a trauma, and (2) there was also an osteomyelitis of the humerus; (3) a four plus Wassermann was present, but treatment with potassium iodid and mercury had no effect. Therefore, Montgomery concludes that the Wassermann by itself is of no clinical consequence.

Ambulatory Treatment of Fracture of Neck of Femur.—The abduction traction apparatus described by Bradford is a modification of the well known Thomas knee splint, to which is added a traction attachment and also a curved padded rod which gives bearing on the descending ramus of the unaffected side, and is bent in such a way as to secure proper abduction. The splint was devised and has been long in use at the Boston Children's Hospital and the Massachusetts Hospital School at Canton as an ambulatory apparatus for the treatment of hip disease. Experiments have shown that as great or greater amount of fixation can be secured by this form of apparatus than by a plaster spica. The apparatus is fitted without difficulty and causes but little discomfort, permitting, if properly shaped, the use of the bedpan without removing the splint. As there are no perineal straps which can be loosened, the apparatus, when applied, is reasonably secure. The apparatus is made with no greater difficulty than the ordinary Thomas knee splint.

With properly applied traction the fragments can be kept in correct position and riding upward is prevented. The results obtained by Bradford in the cases treated with the abduction traction splint lead him to recommend this form of treatment in a large number of cases in this type of injury.

Ohio State Medical Journal, Columbus

- First Stage in Renal, Vesical and Prostatic Surgery. E. H. Harsh, Cleveland.—p. 807.
- Insanity; Influence on Society and Methods of Control. E. A. North, Cincinnati.—p. 810.

Venereal Disease.—Some of the points stressed by Cole are: Do not use injections at the beginning of a gonorrhea—rather treat it as an acute inflammation. Plenty of water and rest in bed are of great value in acute gonorrhea. Do not give alkalis. Clinical diagnosis of chancres is not enough. Substantiate them with dark field illuminator or Wassermann tests or both. Do not wait for a secondary eruption. A negative Wassermann on the blood in an old case of syphilis is not sufficient. Examine the spinal fluid also. The patient taking treatment for syphilis should have frequent examination of the urine to ward off nephritis.

Fractures of Pelvis and Their Complications.—In cases of pelvic fracture Caldwell has never found any other methods of fixation necessary than can be obtained with well adjusted sand bags and adhesive plaster strapping. Buck's extension may be used in cases of double vertical fracture with over-riding of the fragments.

Surgical Treatment of Facial Paralysis.—Fenwick reports a case in which one slip of temporal muscle was inserted into the orbicularis palpebrarum and another slip was inserted into the orbicularis oris to restore lost motion to the eyelid and the lip in these cases.

Destruction of Lice and Nits.—The experiments recorded by Bacot and others, in which sodium chlorid, compound solution of cresol, cresol and kerosene were used, showed that the degree of temperature is the important thing in the delousing process, not the chemical.

Radium in Treatment of Tuberculous Adenitis.—Molyneux is convinced that radium is, if properly used, a safe and certain cure, whether for an early or an advanced case of tuberculous glands. He treated between twenty and thirty cases of every grade with radium. In every case the swellings and even old sinuses faded away. Unless there were already sinuses present, no scars were left. The skin in some instances was a little red for a few weeks from the action of the radium, but this always disappeared. In no case was any ulceration caused.

Experimental Study on Life-History of Sparganum Mansonii Cobbold. T. Okumura.—p. 191.

Leukocytogregarine of Wild Rat.—The parasite described by the authors is believed to be similar to *Leukocytosoon muris*, Balfour, *L. ratti*, *adic*, etc., and possesses many resemblances to *Hepatozoon perniciosum*, Miller. Numerous well made illustrations and a very comprehensive bibliography form a part of this article.

Comparative Value of Bruck and Wassermann Reactions.—One hundred and fifty serums of syphilitic and nonsyphilitic patients, whose cases were clinically diagnosed, were used by Terada in his investigations. Both reactions corresponded in 77.3 per cent. of the cases. In the primary stage of syphilis, Wassermann's reaction was positive in 75 per cent. of the cases; Bruck's reaction was positive in 50 per cent. In the secondary stage of syphilis, the Wassermann was positive in 88 per cent. and the Bruck in 85.5 per cent. of the cases. In the tertiary stage the Wassermann was positive in 86.6 per cent. of the cases, and the Bruck in 80 per cent. of the cases. In cases in which the presence of syphilis was very doubtful, Wassermann's reaction was positive in 39.5 per cent. and Bruck's reaction was positive in 40.1 per cent. In nonsyphilitic cases the former was positive in 12.5 per cent. and the latter in 25 per cent. Bruck's reaction always showed a smaller positive percentage than Wassermann's in each stage of syphilis, while Bruck's reaction always indicated a higher positive percentage than Wassermann's in nonsyphilitic cases. Wassermann's reaction was negative in all cases which had been submitted to arsphenamin injections several times, while Bruck's reaction was positive in two cases among eight. When Bruck's reaction was intensively positive, Wassermann's reaction was strongly positive in many cases, but not always. Owing to the simplicity of the technic and the ease with which Bruck's test can be made, Terada recommends this reaction as an aid in the diagnosis of syphilis when a complicated method, such as Wassermann's cannot be used. However, the decision of a serious question, such as the diagnosis of syphilis, should never depend on Bruck's reaction alone.

Experimental Immunologic Tests of Anti-Influenza Serum.—Influenza immune horse serum was tested by the authors as to its immunologic properties and found to contain certain immune bodies which normal horse serum does not contain. Influenza immune horse serum possesses chiefly antitoxic instead of antibacterial properties. The supernatant fluid of a blood broth culture of influenza bacilli contains soluble toxin, which causes immediate death in experimental animals, while the precipitated bacillary bodies contain the endotoxin which causes hemorrhagic inflammation. Influenza immune horse serum has an antitoxic power against soluble toxin, and very likely also against bacillary toxin. Remarkably satisfactory results have been obtained by the practical application of the serum during the recent influenza epidemic.

Myalgic Pains. J. M. Taylor.—p. 976.
*Modified Operation for Scrotal Varicocele. S. H. Meaker.—p. 973.

Physical Defects Among Male Population.—Comrie's observations would seem to indicate that physical defects worthy of note are present in four fifths of the adult male population. Many of these develop after the age of 18 years; thus three men out of four are fit for general military service at the age of 18, but only two out of four at the age of 23. Many of the defects are preventable or curable—for example, defective teeth, in 20 per cent., varicose veins in 5 per cent.,

hernia in more than 3 per cent., deformities of limbs in 7 per cent., skin diseases in 3 per cent.

Complement Fixation Test in Gonorrhea.—Eight hundred and forty tests were made by Dixon and Priestley on 625 persons sent from both gonorrhea and syphilis wards. Of 53 strong positives, 90.4 per cent. agreed clinically or in history; of 66 moderate positives, 86.3 per cent. agreed clinically or in history; of 75 weak positives, 72.0 per cent. agreed clinically or in history; of 90 doubtfuls, 58.9 per cent. agreed clinically or in history; of 341 negatives, 26.1 per cent. agreed clinically or in history. Twenty-six and one-tenth per cent. of the negatives were cases of gonorrhea or with a history of gonorrhea. Only one case of known gonorrhea remained negative on second test. The authors emphasize that in diagnosis a positive result is strongly indicative of active gonococcal infection. A single negative is of no value, but a second negative in two to three weeks is strong presumptive evidence of absence of infection. Patients doing well show a positive reaction by the ninth or tenth week, which soon begins to fall, such fall coinciding with clinical improvement. Cases in which a strong positive reaction is maintained over several weeks still have an active focus. The administration of detoxicated vaccine in doses of 1,000 millions or more produces an artificial power of fixing complement, which, however, does not necessarily mean any improvement in the patient's condition. In such cases, the complement fixation test is of no value. The complement fixation test should prove of the greatest value in the diagnosis of obscure pelvic diseases in women, so often the result of gonorrhea.

Gunshot Wounds of Chest.—McDougall's experience differs in no way from that of others who have found that the number of persons developing evidences of tuberculosis after chest wounds is exceedingly small. Out of a total number of 1,782 cases of old chest wounds collected from the literature, definite signs of tuberculosis supervened in five, that is, 0.28 per cent.

Treatment of Influenza.—The medical officers at Portland prison treated all the influenza patients with sodium salicylate, ipecac and aromatic spirits of ammonia during the pyrexial stage and tonics during convalescence. Complications were treated as they arose.

Modified Operation for Scrotal Varicocele.—On the basis that the removal of veins is never necessary for the relief of physical symptoms provided the testicle be adequately suspended, Meaker restricts his efforts almost wholly to suspending and supporting the testis. This is accomplished by shortening or reefing the cremaster so that the top of the testicle is brought to the level of the root of the penis. This is accomplished by eight interrupted sutures of fine catgut, and making no attempt to bring the ligated ends together. The next step is the shortening of the cremaster.

Case of Lymphosarcoma of Both Suprarenals.—Aside from the fact that both suprarenals were the seat of a tumor, the point of special interest in Burnell's case was the fact that clinically it resembled a case of intussusception, and the patient was operated on for this supposed condition. The tumors were discovered at the necropsy.

*Cyclopean Microphthalmos. G. Van Duyse.—p. 1. Conc'n.

*Cervical Ribs. M. Dubois.—p. 40.

*Treatment of Ulcerating Cicatrix. Derache.—p. 60.

*Testicle Implantation. J. Voncken.—p. 64.

Cyclopean Microphthalmos.—See summary of Van Duyse's article on page 1963 of the last volume.

Cervical Ribs.—Dubois reports three cases, but the disturbances from the supernumerary ribs were not pronounced enough to warrant operative interference. Two of the patients were men of 39 and 60, with pains and impotence in one arm. They had been noted for six months in one case and twenty years in the older man. He was a pianist and could not play for more than half an hour at a time. There was a pair of cervical ribs in this case. The third patient was a woman of 29, and a pair of cervical ribs had induced the complete Claude Bernard-Horner syndrome. The condition was found unaltered when reexamined six years later. The diagnosis of cervical ribs is generally made only by exclusion but roentgenoscopy confirms it. Pains, atrophy, circulatory disturbances and paresthesias should suggest a supernumerary rib, especially when the smaller muscles of the hand are affected; or there may be symptoms suggesting paralysis of the cervical sympathetic. He reviews the literature on operative intervention.

Ulcerating Cicatrix.—Derache describes his success in curing chronic suppuration when a war wound has ulcerated after apparent healing. In seven cases he made incisions around the cicatrix, in sound tissue, cutting down through the subcutaneous layers, and sometimes making a double row of these circumferential incisions. This technic has proved its usefulness for old varicose ulcers.

Testicle Implantation.—Voncken reviews what has been accomplished in this line, citing Lydston's work and Steinach's experimental research, the clinical case reported by Steinach and Lichtenstern, and Rohleder's experimental and clinical experiences with treatment of homosexual perversion. He then describes Voronoff's "painstaking experimental research carried on for more than a year at the Collège de France. He studied on sheep and goats the influence of transplantation of testicle tissue. He found it easy to follow by the external manifestations the changes in the functioning of the internal secretion of the testicles." Castration of a young goat arrested the development of the horns. He conducted three series of experiments: In the first series, testicle implantation in the young castrated animals restored in a short time their normal vigor. The growth of the horns, arrested by the castration, began anew as soon as the implant had grown into intimate connection with the adjacent tissues. In his second series of experiments implantation of testicle tissue in females transformed their character: Gravid goats were delivered normally, but they exhibited marked repulsion for suckling their young and other maternal cares. The testicle implant seemed to stifle all the instincts of maternal affection. In his third set of experiments, he implanted the testicle tissue in rams and goats 14 to 15 years old. This age in these animals corresponds to the human age of 65 to 70. The senile animals, with sluggish reactions, underwent a radical transformation within periods ranging from a few days to three weeks after the implantation of the testicle graft. Voncken emphasizes that the photographs which Voronoff exhibited with his report at the recent Congrès de chirurgie at Paris testified most significantly to the truth of his statements. One of the goat bucks impregnated a female.

"Counter experiences were equally significant," he adds, "removal of the graft reducing the animal to his former senile condition. A new implantation restored anew *les avantages de la jeunesse*. In view of such an ensemble of facts," Voncken comments, "can one doubt further the preponderant influence of the internal secretions of the testicle on senile phenomena?" He adds that Voronoff's histologic study of the grafts showed that the vessels growing into the graft do not reach the center in time to perpetuate its vitality. The center dies and is resorbed; only the periphery

retains its vitality. Hence small grafts take better than large ones. He only succeeded in keeping two alive out of thirty whole testicles implanted, while the partial grafts were constantly successful. A number of small grafts can be implanted under the skin in any part of the body, or in the peritoneal cavity, or under the vaginalis in the scrotum. He found this latter technic the most reliable. Voncken adds that Lydston's experience has given a practical confirmation of the experimental results thus realized in the laboratory. "Organotherapy is invading more and more the different chapters of pathology, and this surgical opotherapy seems to augur a fruitful future which is only the natural sequence of the marvelous results already realized with transfusion of blood." He suggests the possibility that grafts of thyroid tissue might be used in treatment of cretinism. "With any endocrine insufficiency, some harmless surgical intervention might definitely restore the organic balance." (Voronoff's report of improvement in a case of myxedema after implantation of monkey thyroid tissue was summarized in THE JOURNAL, Aug. 29, 1914, p. 810.)

The Hemostatic Apparatus of the Human Uterus.—This issue of the *Archives* is accompanied with a set of nineteen fine plates which were omitted by mistake from Keiffer's article on this subject in the issue for June, 1919.

*Hysterectomy with Suppurating Adnexa. J. L. Faure and L. Bégouin. —p. 417.

System for Care of Prospective and Nursing Mothers at the Creusot Factories. M. Bourret.—p. 448.

*Roentgen Treatment of Uterine Fibroma. Bécélère.—p. 453.

Hysterectomy with Suppurating Adnexa.—Faure and Bégouin say that each surgeon has his own method, but these methods often conflict with the laws which fifteen years of experience have impressed on them. With virulent lesions, the pelvis scattered with pus pockets, the patient feverish, vaginal hysterectomy may work a miracle when abdominal hysterectomy would be too risky. Under other conditions, abdominal hysterectomy is called for whenever there is bilateral adnexitis rebellious to medical measures, becoming chronic, and causing pain and other disturbances. Even when direct inspection fails to reveal any lesions in tube or ovary on one side, if they are painful, they should be removed with their suppurating mates, unless the patient prefers to take the chance of a second operation later. In the majority of cases, the cervix is not diseased enough to warrant its removal. Leaving the cervix simplifies the hysterectomy materially. The adhesions that form around the suppurating adnexa are high up in the pelvis, and the depths of the pouch of Douglas are generally free, so that planes of cleavage there allow the easiest means of working the adnexa loose. They can also be readily detached from the broad ligament in front of them. The adnexa should thus be attacked from below upward, from the front backward, and from within outward. This not only facilitates detaching the adnexa but there is less danger of injuring the ureters. Section of the cervix is the key to the whole procedure, as this is the lower pole of the fused uterus-adnexa mass. Hemisection of the uterus may be advisable besides, in difficult cases. They give six illustrations showing the various methods to meet varying conditions.

Roentgen Treatment of Uterine Fibromas.—Bécélère concludes from his 400 cases of roentgen-treated uterine fibromas that, aside from certain conditions which imperiously demand surgical intervention, roentgen therapy is applicable to all fibromas of the uterus, without restrictions of any kind. His experience has demonstrated that radiotherapy arrests the development and induces more or less complete retrogression before 40 as well as after 40, with large as well as with small fibromas, and in women with normal menstruation as well as with excessive uterine hemorrhages. He gives weekly exposures with moderate doses. The rays are applied in turn from the right and left of the median line, just above the horizontal ramus of the pubis. If the tumor is very large, more fields may be exposed. Each

exposure is limited to a circular surface 10 cm. in diameter, through a leaded glass cylinder, resting on a thin disk of wood. The rays are filtered through 5 mm. aluminum; the dose for each field is 3 H. units. In 60 per cent. of the cases from 12 to 14 weekly exposures were required; in only six cases from 31 to 50. In the more favorable cases the upper pole of the fibroma shrinks down nearer the pubis by 1 cm. a week. This shrinking in size is usually apparent by the third and sometimes by the second exposure.

*Local Serotherapy of Gonococcus Rheumatism. R. Debré and J. Paraf.—p. 908.

*Case of Gonococcus Polyarthrit. H. Dufour, and others.—p. 918.

Atypical Spirochete Jaundice. M. Villaret and others.—p. 920.

Paget's Osteitis.—Marie and Léri describe peculiar anomalies found in the skull in persons who have had Paget's disease.

The same writers report further the unexpected discovery of extensive syringomyelia at necropsy in a case of Paget's disease. They theorize to explain this by mechanical factors.

Hippocratic Fingers.—The nails had grown to assume this type during the months an arteriovenous aneurysm had been forming in the upper arm.

Serotherapy of Gonococcus Arthritis.—Debré and Paraf say that the experiences with local serotherapy in meningitis encourage similar local measures in gonococcus arthritis. They found that intra-ocular injection of anti-gonococcus serum promptly cured the lesions induced by direct injection of gonococci into the anterior chamber of the rabbit eye. The account of their experimental anti-gonococcus serotherapy is soon to appear in the *Annales de l'Institut Pasteur*. The results were so encouraging that they injected the antiserum in 15 patients with different forms of recent gonococcus rheumatism. These cases are described in detail; in all the joint disease was severe, and without the local serotherapy would have probably terminated in ankylosis after weeks of fever and pains. In 6 cases the cure was complete in less than eight days; in 8 others before the fifteenth day. In all these 14 the joint functioning was normal. In one case no benefit was derived. The woman was pregnant and in bad general condition.

They punctured the joint and injected the antiserum in place of the evacuated effusion, repeating this every day or second or third day, applying afterward a compressing dressing. In 6 of the cases several joints were affected, and they were all injected with the antiserum at the same time. This local serotherapy has to be supplemented with intramuscular or intravenous injections of the antiserum for the general effect and to ward off involvement of other joints. This local serotherapy is limited to the larger joints, as it is practically impossible to inject the antiserum into a small articulation. They say they have never seen anything to indicate that there are special strains of gonococci.

Differentiation of Gonococcus Arthritis.—Dufour remarks that when it is difficult to tell gonococcus polyarthrit from acute articular rheumatism, pressure on the intra-articular ends of the bones will decide the question. This causes pain with gonococcus lesions, but not in acute rheumatism. In

three recent cases roentgenograms showed definite changes in the bones, which explained the pain. The multiple arthritis in these cases had developed five and ten days after the first symptoms of gonorrhea or after supposed recovery from gonorrhea. All three recovered completely. The roentgen findings in two cases of acute articular rheumatism failed to reveal any similar changes in the bones.

*Dissociation of Pain. A. Le Dantec.—p. 451.

Dissociation of Pain.—Le Dantec's study of the electric sensibility of the normal skin and of the pain in war wounds has revealed an unsuspected dissociation of sensations. The different forms of the electric current elicit different sensory responses, as he explains in detail. This, he says, gives a basis for treatment of pain. The article is concluded in the following issue.

Paris Médical

Nov. 8, 1919, 9, No. 45

*Early Reparative Surgery. P. Descomps.—p. 369.

*Diagnosis of Aortitis. A. Mougeot and Pacaud.—p. 374.

*Clinical Signs of Typhus. A. Porot.—p. 380.

Early Reparative Surgery.—Descomps reports 91 per cent. successes in 451 cases of war wounds treated by primary suture, but he explains how impossible this is as a rule in the wounds of peace times. It is rare that surgical intervention is practicable at once. Retarded primary reunion is therefore the practitioner's reliance for early reparative surgery. This is the more necessary as the prudent physician would prefer to wait for the clinical and bacteriologic findings after excision. Two or three days' delay will permit this, so that retarded primary suture is destined to be the method of choice or necessity. It is now a regular classic method, and every one should be familiar with its indications and technic. He warns to be prodigal in cutting out crushed tissues but to be stingy in débridement. After excision, he cleans the focus with ether; whenever the wound allows he gives it a prolonged bath of ether, repeating this several times, allowing the ether to evaporate each time.

Differential Diagnosis of Aortitis.—Mougeot and Pacaud declare that the actual topography of the descending portion of the thoracic aorta differs from the recently published descriptions in several respects. They give some roentgenograms and arguments to correct the discrepancies.

Typhus.—Porot reiterates that of all infections, typhus seems to be the one with the greatest affinity for the nervous system. The clinical picture is that of an eruptive fever with tox-infection, striking predominantly the nervous system as the cerebrospinal fluid testifies.

Nov. 22, 1919, 9, No. 47

*Orfila and the Toxicology of Arsenic. Balthazard.—p. 401.

*Postoperative Colic Pains. A. Schwartz.—p. 411.

A Pioneer in Toxicology.—Balthazard gives a historical sketch of the first incumbent of the chair of legal medicine in the Paris medical school, Orfila (of Spanish birth), and a celebrated poisoning case in which he had to invent tests and methods to detect the arsenic in the tissues, and thus laid the foundations for modern toxicology.

Postoperative Colic Pains.—Schwartz has been delighted with his success in warding off and curing postoperative colic pains by applying a bag of ice to the abdomen. He has the ice bag large enough to cover the entire abdomen, and keeps ice in it all the time. The cold seems to prevent the spasms almost inevitable otherwise, while it does not check peristalsis, and the gases escape. He keeps it on generally for about twenty-four hours, applying it first the day after the operation, after the close of the phase of the "absolute silence" of the first few hours.

*History of Grafts in Man and Animals. Maucclair.—p. 661.

*Epilepsy a Coma, not a Convulsion. P. Hartenberg.—p. 664.

Grafts of Tissues.—Maucclair reviews the history of tissue grafts from the description of rhinoplastics in the Vedas down to Tagliacozzi of Bologna in 1580, who reconstructed the nose from a pedunculated flap from the arm, and others' experiences, bringing his long list down to date. His analysis shows that the question of grafts is still quite complex and is not so simple as it might appear. The surgeon has to be guided by the biologist and not by mere empiricism. Grafts heal in place better when the tissue is taken from consanguineous subjects. Just as in transfusion of blood the blood of donor and recipient should be of the same class, it might be well to select consanguineous homografts. The future of grafting operations opens wonderful vistas, thanks to this symbiosis between the biologist and the surgeon. But, he adds, we must advance only by solidly established facts, and not take our wishes for realities, but wait patiently but hopefully for progress and results.

Epilepsy.—Hartenberg entitles his communication "A New Conception of Epilepsy," as he insists that the main features of the epileptic seizure are not the phenomena of excitation but those resulting from the arrest of the functioning of the brain. This inhibition of the cortical centers dominates the clinical picture, and not the convulsion, as he explains in detail. Experimental research has shown that any sudden inhibition of brain functioning causes unconsciousness first and then muscular movements. All the data exclude spasmophilia as responsible for epilepsy, while they all fit perfectly into the assumption of inhibition of cerebral functioning, with its secondary inevitable muscular play of movements. Sleep arrests the activity of the brain and favors inhibition, and thus explains the frequent predominance of the severer seizures at night. Strychnin tones up the neurons and six epileptics who are taking strychnin have had their seizures remarkably attenuated, some having had no return for one to three months of their weekly seizures. If the seizures were due to primary excitation of the motor centers, as generally assumed, strychnin would increase and aggravate the seizures. But the exact reverse was realized. Unfortunately, he adds, this effect does not last long; the system becomes accustomed to the strychnin and it ceases to influence the seizures. Epilepsy he defines as a paroxysmal abolition of the higher functions of the brain. Not the convulsion but the coma is its essential element.

*Surgery of the Large Intestine. J. Okinczyc.—p. 681.

*Differentiation of Disease in Stomach and Liver. G. Leven.—p. 684.

*Treatment of Blackwater Fever. Houssiau.—p. 685.

Fixation of Cecum and Colon.—Okinczyc's study of cecopexy and colopexy is accompanied by fourteen illustrations of the preferable technics.

Differentiation of Disease in Stomach and Liver.—Leven comments on the intimate connection between the biliary passages and gallbladder and the region of the pylorus and duodenum, and the close reflex connection between the biliary and the gastric regions. Disease in one is liable to hide under the mask of the other, but differentiation is possible by a course of treatment which will soothe the pains, relax the spasms and abolish the reflexes, and thus leave nothing but the organic lesions if there are such, and enable them to be correctly located. He describes this "therapeutic test" in detail. Absolute repose for body and mind is indispensable, bedrest the first week, dieting, and sodium bromid in the middle of two meals for five days, and then supplemented with bismuth every two hours for twenty days. Moist heat should be applied to the abdomen while in bed, and for five or six hours daily after getting up. The whole course is thus the systematic elimination of everything functional and reflex, and in two, three, or four weeks the previously baffling diagnosis is clear.

Blackwater Fever.—Houssiau noted two distinct types of this disease in his twenty cases. In the hemoglobinuria-

developing in the course of very severe malaria, treatment must aim to attenuate the malaria, and quinin must be pushed. With this form there are vomiting, chills, high fever, scanty and pink urine, pulse regular but fast, and heart sounds normal. The other type develops in the course of chronic malaria, from some secondary cause. The urine is black and abundant at first, the pulse and heart sounds weak, and treatment must aim to sustain the heart as the main thing. In both forms, death may occur from anuria. Drugs should not be given by the mouth with anuria. Massive injections of camphorated oil, large enemas, and hot packs are useful. The prognosis is grave but not inevitably fatal. Recovery occurred in one of his cases after fifty hours of anuria.

Opening Lecture of Gynecology Course. J. L. Faure.—p. 701.
Universal Automatic Retractor. E. Juvara.—p. 706.

Anaphylaxis as Factor in Epileptic Seizures.—Pagniez and Lieutaud here announce that they have applied to epilepsy the treatment by antianaphylaxis which has proved effectual in treatment of certain cases of urticaria, circumscribed edema, migraine and other phenomena of anaphylaxis of alimentary origin. In persons subject to these, the anaphylactic phenomena are preceded by changes in the blood, the *crise hémoclasique initiale*, as Widal calls it. This testifies to the anaphylactic nature of the disturbances, and this is confirmed by the warding off of the disturbances when a small amount of the substance responsible for the anaphylaxis is ingested before the regular amount is eaten. (Previous communications on the subject have been summarized in these columns, May 24, 1919, p. 1577, and Aug. 16, 1919, p. 562).

Studying epileptic seizures from this standpoint has shown that if certain epileptics eat a little more than usual of a certain food, the number of leukocytes is liable to drop and there may be an actual hemoclastic crisis, and within a few hours a typical seizure. One case is described in detail. The robust epileptic of 18 with the mentality of an illiterate of 14 was tested with a cup of chocolate, 50 gm. after his usual meal, and a seizure followed. Ten days later the experiment was repeated only that forty-five minutes before the meal he took 50 cg. of pulverized chocolate in a cachet, and there were no seizures for several days. The circumstances otherwise the same, he was given then 60 gm. chocolate after a similar meal. A pronounced hemoclastic crisis followed, the leukocytes dropping from 11,000 to 5,400, while the maximal arterial pressure wavered, and during the night there were three seizures, and a total of eight during the following nine days. Then the experiment was repeated, only with preliminary ingestion of 50 cg. of the chocolate. No hemoclastic crisis followed and no seizures during the ensuing week. Similar experiments on normal subjects showed no change in the blood picture except the physiologic digestion leukocytosis. But whenever the young epileptic took the 50 or 60 gm. of chocolate, either with or without the preliminary dose, the leukocyte count showed pronounced fluctuations, the mononuclears increasing. The meal otherwise consisted of 250 gm. of bread, 200 gm. of meat and vegetables and 250 c.c. of linden flower tea. The effect of the antianaphylaxis measures apparently confirms the correctness of the premises. Similar experiments were repeated on a few other epileptics, with analogous results.

Prophylaxis of Tuberculosis—Mouisset discusses why tuberculosis is more prevalent than any other disease, and reiterates the necessity for and the success in warding it off by keeping the resisting forces up to par. This should be taught from the earliest childhood. He remarks parenthetically that one of the few agreeable surprises of the war was the small proportion with open tuberculosis among the French soldiers returning from imprisonment in Germany. Only 14 per cent. in two groups of 15,000 each, and only 3 or

5 per cent. in an advanced stage. He suggests that the enforced abstention from alcoholic excesses may have had something to do with this.

Paradental Cysts.—Jacques insists that the diagnosis of paradental cyst in the upper jaw is not difficult if the possibility of such a lesion is borne in mind. It is usually mistaken for sinusitis.

Progrès Médical, Paris

*Sarcoma of the Stomach. M. Loeper.—p. 455.

Technical Points in Mycology. A. Sartory.—p. 458.

Trocar for Lumbar Puncture. P. Delmas.—p. 460.

Sarcoma of the Stomach.—Loeper describes a case of gastric sarcoma in an African soldier. The differential diagnosis of these tumors is based on the hour-glass shape of the stomach and the presence in the stomach contents of round cells which are elements of the sarcoma, but are liable to be mistaken for lymphocytes. Fourteen out of 22 operative cases of sarcoma on the outside of the stomach had survivals up to three years. The outlook is much less favorable when the sarcoma develops inside the stomach or works through the wall into and through the mucosa. Only 4 recoveries are known in 19 operative cases of this type. He expatiates on the importance of cytologic examination in all cases of suspected gastric tumors.

Epidemic Influenza. G. Vernoni.—p. 325.

Hypertrophic Cirrhosis of Liver with Extreme Hypertrophy of Spleen. G. Antonelli.—p. 347.

Recent Progress in Knowledge of Internal Syphilitic Disease.—In the course of this long study of recent achievements in this field, Pontano comments on the information sometimes to be derived from the Herxheimer reaction. For example, in one case heart block developed after injection of arsphenamin, revealing an unsuspected localization of the infection. The mitral valves are always spared, but the aortic valves may suffer from the extension of syphilitic aortitis. Romberg says that this latter does not develop until from four to forty-three years after infection. In his

278 cases the average interval was twenty years. Syphilitic aortitis should be suspected, he says, when there are pains and a sensation of oppression back of the sternum, a systolic murmur at the aorta, accentuation of the second aortic sound, and marked relief in the orthodiagram of the left and upper portion of the arch. The pains are of the compression type, and are referred to the upper part of the sternum, radiating to the shoulders and arms, especially to the left, to the neck and the interscapular region. These pains usually are noticed after exercise or copious eating or drinking, but sometimes they come on independently of such factors and even in the night. The modification in the sounds is connected with the changes in the valves and the dilatation of the arch which brings it closer to the wall of the chest. Romberg asserts that accentuation of the systolic murmur may precede the dilatation of the arch as detectable by roentgen examination, and thus may be the first and the only sign of the aortic disease. It should be ausculted, the patient supine, in the first or second intercostal space. The strong second sound differentiates this murmur from that with aortic stenosis in which the second sound is scarcely perceptible. These auscultation findings were manifest in 75 per cent. and the pains in 50 per cent. of his cases. The pains from aortitis may be followed by symptoms of angina pectoris from extension of the process to the mouth of the coronaries. In the early stages of syphilis, Pontano adds, the symptoms from the heart are usually functional and transitory. In 200 soldiers with secondary syphilis, hypacidity was found in 60 per cent., anacidity in 18 and hyperacidity in 17 per cent. Lesions in the liver from any cause are liable to exaggerate the production of antibodies, so that serologic tests may give a positive response even in the absence of syphilis. He says of tabes and general paralysis that experience is confirming more and more the fact that very mild syphilis is particularly liable to be followed by them as it receives only irregular or irrational or no treatment. He reiterates that there is no morbid condition of the central nervous system or the meninges which may not be simulated by syphilis, but the instability of the symptoms, their brief duration and tendency to recurrence are suggestive of the syphilitic nature.

Treatment of Hemorrhoids.—Grande describes an automatic pumping arrangement which drives the blood out of the turgid veins in the hemorrhoids by the action of compressed air. As the blood is expelled, the hemorrhoids return into the bowel. After defecation the patient sits down on a special metal cup with a valve which compresses the air. It is possible that the veins might recover tone, and the tendency to hemorrhoids be abolished in time by this compressed air massage.

War Wounds of Bones and Joints. R. Bompani.—p. 297. Cont'n.

Rat-Bite Disease.—Bergamini describes a case of sodoku in a soldier free from inherited or acquired taints and intoxications. The Wassermann reaction was positive, and the young man threw off the disease under arsphenamin after the failure of all other measures.

Purpura Simulating Appendicitis.—This case teaches that purpuric patches or edema at the ankle, knee or elbow should warn not to operate without further consideration when intense abdominal pain and fever suggest appendicitis or perforation of the bowel or intussusception. The fever and the location of the intense pain in the boy of 11 simulated appendicitis, but the purpuric patches were discovered in time. The abdominal pains in these cases of peliosis or purpura rheumatica are evidently from hemorrhagic

poussées in the viscera. Even without the petechial exanthem, pains in the joints and edema or even simple rheumatic pains should warn of the necessity for caution in operating, and for symptomatic treatment as for hemophilic states in general.

Crónica Médico-Quirúrgica, Havana

August, 1919, **45**, No. 8

*Ocular Complications of Influenza. F. M. Fernández.—p. 232.

September, 1919, **45**, No. 9

*The Victory Meeting of the A. M. A. F. M. Fernández.—p. 251.

Ocular Complications of Influenza.—Fernández states that among his hundreds of influenza cases he encountered only 6 in which there was iritis from toxic action (2), or the optic nerve and papilla (2), or the angle of filtration (1), were suffering from the same toxic action. In the sixth case the corneal ulcer might have been merely a coincidence, but it might have been the direct work of the influenza infection. The patients were all men between 19 and 40, and 4 recovered under the usual local measures. One man was left with incipient atrophy of the optic nerve, and in another case the choked disk accompanying sinusitis only partially retrogressed.

Victory Meeting of the A. M. A.—The editor-in-chief of the *Crónica* (and also of the *Revista cubana de oftalmología*), Dr. F. M. Fernández, was the official delegate from Cuba to the Atlantic City meeting, and he reproduces the program entire with running comment on many of the communications presented in the various sections. He thus comments on practically all in the section on ophthalmology.

*Lethargic Encephalitis in Guatemala. F. Arana G.—p. 100.

Influenza in Guatemala. M. Y. Arriola.—p. 104.

Yellow Fever in Guatemala.—Madrid relates the particulars of the recent epidemic of yellow fever and the way in which it was stamped out. He emphasizes the absence of prodromes, and the primary vasoconstriction with congestions, followed by the vasodilatation responsible for the hemorrhages.

Lethargic Encephalitis.—The woman of 36 was supposed at first to be drunk when she was brought to the hospital, and she slept continuously for five days, with slight fever but no other symptoms. Under mercurial treatment, facial paralysis and ptosis developed, and the somnolency became more intense, with mild delirium at times. Lumbar puncture showed the tension and albumin content slightly above normal. The fifteenth day hexamethylenamin was given systematically by the mouth, and 1 gm. of peptone was injected by the vein. This was repeated with one day intervals six times. The reaction was severe, with chill and fever, but by the second injection great improvement was manifest. The twenty-sixth day lumbar puncture still showed high tension but the fluid was otherwise normal. By the fifth or sixth week recovery was complete, with no traces of the disease and no memory of any of the weeks of the somnolency. There had been no bulbar paralysis, vertigo or vomiting at any time. Arana ascribes the favorable outcome in large part to the proteosotherapy.

***Syphilis as a Factor in the Eye Complications of Typhus.** A. Torres Estrada.—p. 62.

Syphilis as Factor in the Eye Complications of Typhus.—Torres has encountered six cases in which typhus was accompanied by ocular lesions. In all they resembled closely the lesions of syphilis. The optic neuritis progressed to blindness in four of the six cases. One of the others had inherited syphilis, and after having been totally blind for a time after the typhus, under mercury and iodid he regained considerable visual acuity in both eyes. Torres witnessed also a number of similar cases of optic neuritis following influenza, and retrogressing likewise under specific treatment.

Euphorbia as Diuretic. Manuel Galdós.—p. 117.

***Headache in Children.** R. Argañaraz.—p. 118. Cont'd in No. 13, —p. 130.

Chronic Pancreatitis with Tardy Inherited Syphilis.—The case in a young man here reported is the only one of which the writers could find record in which chronic pancreatitis subsided completely and permanently under treatment for tardy inherited syphilis. The clinical picture did not differ in any respect from that of ordinary sclerosis of the pancreas, but the improvement under specific treatment proved the touchstone of its nature. The young man had been married three years and had a healthy child.

Fatal Amebiasis.—A previously supposedly healthy man of 30 suddenly developed symptoms of coloreticitis with peritonitis the fifteenth day, and death five days later, from necrosis of the cecum and part of the ileum. The ameba in this case had required only twenty days to induce innumerable ulcerations and perforations, with extensive necrosis not only of the bowel but of adjacent muscle.

Headache in Children.—Argañaraz refers to headache from intermittent loss of balance between the sensory and motor functions of the eyes. The trouble is merely from unbalanced growth, as the eyes do not always develop parallel. The position of the eyes in functional balance differs from the position in anatomic balance, that is, in repose. This position in repose is what is often responsible for the headaches in children between 5 and 12, that persist after defects in refraction and muscular balance have been corrected. He explains how it is possible to detect this anomaly and correct it by the use of weak prisms with the base inward. The headaches subside at once when this is done, as he shows by the details of eight typical cases.

***Treatment of Ankylosis of the Knee.** A. Ceballos.—p. 121.

Etiology of Influenza. R. Kraus.—p. 126.

***Access to Bones Through the Calv.** R. Finochietto.—p. 129.

Dissociation of Bile Pigments. C. P. Waldorp.—p. 131. Begun in No. 11, p. 109.

Ankylosis of the Knee.—Ceballos reviews the ultimate outcome in seven cases of ankylosis of the knee corrected by an operation before 1917. The ultimate outcome has been so satisfactory that he declares operative correction should be undertaken not only for angular but for straight stiff knees. He prefers a pedunculated flap of aponeurosis to interpose, but has used both free and pedunculated flaps, and the results were equally good with both. Gonococcus ankylosis of the hip joint is usually harder to cure than the traumatic, as the margin of the acetabulum is generally damaged, which favors secondary displacement. A year at least must elapse after the infection, as the vitality of the gonococcus is so

great. He followed Murphy's technic for the knee, and begins at once to apply extension to both legs. Illustrations are given of the device for passive exercise of the suspended joint by the patient himself.

Access from the Rear to the Bones of the Leg.—Finochietto gives an illustrated description of the large U-shaped flap which he turned back on the calf to the knee for access to a huge osteoma. The flap was readily replaced after the tumor had been removed.

***Teratomas in the Thorax.** D. Staffieri.—p. 255.

School Colonies and Vacation Schools. C. Muniagurria.—p. 260.

***The Ideal for the Fight Against Tuberculosis.** A. Martelli.—p. 271.

Teratomas in the Chest.—Staffieri adds another to the less than 100 cases of intrathoracic teratomas on record. They have been found at all ages, but they generally make themselves manifest first during the rapid growth at puberty. In only four of the cases on record was the surgeon able to remove the teratoma completely; the others had to be content with evacuating the contents and draining. Most of the patients were left with a fistula. In some of the nonoperative cases the cyst underwent malignant degeneration, and as there is always danger of fatal compression or other injury from the teratoma, it should always be operated on. In the personal case described the woman of 33 had been having pains back of the right breast for seven years, with a recurring cough and blood-stained expectoration. In the last two years she had often found hairs in the sputum but there had never been fever. The operation confirmed the assumption of a teratoma opening into a bronchus, and recovery was soon complete except for a small fistula.

The Ideal Prophylaxis of Tuberculosis.—An important national conference has recently been held at Rosario to discuss the prophylaxis of tuberculosis. The transactions and resolutions adopted are given in this issue of the *Revista*. Martelli urges the general adoption of vaccination against tuberculosis as the ideal method of prophylaxis, citing Maragliano's experiences with it.

Semana Médica, Buenos Aires

Aug. 21, 1919, 26, No. 34

***Motor Plastic Operations.** G. Bosch Arana.—p. 191.

***Voluntary Mutism.** F. F. Morice.—p. 208.

***Syphilitic Hemiplegia.** O. E. Adorni.—p. 211.

Fracture of the Elbow. R. A. Rivarola.—p. 216.

Motor Plastic Amputations.—Bosch Arana discusses the general principles and the practical application of means to impart volitional control to artificial limbs by plastic devices. He thinks this vitalization of prostheses has a future beyond anything now anticipated. In this article he does not describe his extensive personal contributions to the subject, reserving this for a later article.

Voluntary Mutism.—The man in question is a docile inmate of the public asylum for the insane. He has persisted for seventeen years in his refusal to speak. This is the first case of prolonged aphasia published in Argentina.

Syphilitic Hemiplegia.—Adorni's patient developed suddenly flaccid paralysis of the right arm and leg and left facial paralysis. The rapid recovery under mercurial treatment confirmed the suspected syphilitic nature of the paralysis.

Subtilis Infection of Eye. E. B. Demaria.—p. 221.

***Reconstruction of Biliary Passages.** E. Nicholson.—p. 223.

***Technic for Partial Colectomy.** G. Palacios.—p. 229.

***Infanticide.** Antonio D'Alessandro.—p. 231.

***Syphilis in Argentina.** Manuel Beatti.—p. 235.

***Teaching of Sexual Hygiene for the Young.** L. Bard.—p. 237.

***Commercial Aviation.** J. A. López.—p. 239.

Reconstruction of Biliary Passages.—Nicholson reviews recent literature on this subject, and describes a personal case of gallstone disease of five years' standing in which several operations were required to correct conditions.

Megacolon.—Palacios describes two cases with successful partial colectomy.

Infanticide.—D'Alessandro makes a plea for arrangements permitting infants to be clandestinely abandoned without immediate injury to the infant. His text for this arraignment of present conditions is a local news item to the effect that four infant cadavers were found in a single day in the same district of the city.

Syphilis in Argentina.—Beatti protests against the assumption of the extreme prevalence of syphilis. He obtained a positive response in only 13 per cent. of 2,400 applications of the Wassermann test to the blood and spinal fluid.

Sexual Hygiene.—Bard refers to the necessity for lectures in the high schools and colleges on the prophylaxis of venereal diseases, as these diseases are so often acquired between 16 and 20. The lectures should be given preferably by the professor of anatomy. The task cannot be left to the parents; for one reason, among the many, because the parents are themselves too ignorant.

Commercial Aviation.—In this eighth instalment of his study of the psychophysiology of the aviator, López discusses the difference between conditions in war and in commercial aviation. He emphasizes the necessity for strict medical tests for commercial aviation or accidents will destroy the public's confidence in it.

The Medicolegal Conception of Deformity. Jesús Canseco.—p. 929.

*Serodiagnosis of Typhus. J. Blanco and M. Tapia.—p. 931.

*Coagulation Time as Element for the Prognosis. M. Corachán and F. Gallart Mones.—p. 935. Conc'n in No. 3439, p. 960.

Serodiagnosis of Typhus.—Blanco and Tapia obtained pronounced agglutination with the proteus X in thirty-three cases of typhus, in one case at 1:1,000 as early as the third day. In one case the agglutination at 1:1,000 continued up to a month after defervescence.

Coagulation Time and the Prognosis.—Corachán and Gallart comment on the importance of recording the coagulation time of the blood before operating, to be warned of any tendency to hemorrhage or to thrombosis. A family tendency to hemophilia or to thrombosis—a history of phlegmasia alba, of phlebitis, etc., in any member of the family—is also instructive, but the coagulation time of the patient's blood is more certain. They use Bloch's citrated blood-calcium chlorid technic, and in 56 cases thus tested they found that coagulation occurred abnormally fast in 2 and abnormally slow in 18. Ingestion of 3 or 4 gm. of calcium chlorid daily before the operation brought the coagulation time up to normal. When this was not done the operative and postoperative losses of blood confirmed the warning from the coagulation index. They found a normal coagulation index in their cases of venous thrombosis; this suggests that other factors, such as infection, cooperate in thrombosis. In 2 cases of gangrene of the feet, no modification of the abnormally slow coagulation could be realized, even with systematic calcium chlorid and gelatin treatment.

Influenza in Danish Army. L. Ammentorp.—p. 1161.

Oct. 22, 1919, 62, No. 43

*Vaccine Treatment of Gonorrhea. H. Boas and O. Thomsen.—p. 1185. Blood Platelet Extract for Hemorrhage. E. Als.—p. 1190.

Oct. 29, 1919, 62, No. 44

*Gas Phlegmon in Femur. H. C. Hall and M. Kristensen.—p. 1209.

Vaccine Treatment of Gonorrhea.—Boas and Thomsen tabulate the results of treating recent uncomplicated gonor-

rhea in men with a vaccine made of twenty-four hours' cultures of several strains of gonococci on ascites-agar plates in 0.9 per cent. saline. In 202 cases not treated with the vaccine, 45 per cent. developed complications, but only 19 per cent. developed complications in 126 treated with the vaccine. The outcome was in reality even more favorable than this, as in 7 of the 23 complication cases a vaccine had been used which proved later to have been defective. The complications in the vaccine cases were very mild; there was prostatitis only in 3, while in the nonvaccine cases prostatitis formed half of the 90 complication cases.

Gas Phlegmon in Femur.—Both the Welch bacillus and *Bacillus phlegmonis emphysematosae* were cultivated from the phlegmon in the femur in the two young men. Infection had presumably occurred from the needle during an injection of caffeine.

*Indications for Prostatectomy. Torsten Rietz.—p. 837.

Hypernephroma in Center of Kidney. Nils Stenström.—p. 843.

Indications for Prostatectomy.—Rietz states that the mortality with prostatectomy in Sweden still averages 11 or 12 per cent. even with the best surgeons. In England and America, he adds, the mortality is lower, but in some of the German clinics it is still higher. Analysis of some of the fatal cases showed pathologic conditions in the kidneys in an unexpectedly large proportion, and probably many of the cases recorded as heart disease may have been primarily disease of the kidneys. These facts suggest the importance of ascertaining the functional capacity of the kidneys before attempting any operation on the prostate, and he has been systematically investigating this since the beginning of 1918. He has now a record of 18 cases thus investigated by himself and 9 by Kjellgren—a total of 27 cases, and the outcome has brilliantly confirmed the information thus derived. He selected the water test as the simplest and a very reliable means for functional diagnosis. The patient drinks 1,000 c.c. of water, fasting, at 8 a. m. and the urine is collected at hourly intervals till 12 and then at 3, 6 and 9 p. m. and the night urine till 8 a. m. With this systematic research he found that the patients fell naturally into five groups, as he explains in detail, and the outcome of the cases confirmed the accuracy of the data thus acquired.

Ugeskrift for Læger, Copenhagen

*Significance of Bile Pigment in the Serum. E. Meulengracht.—p. 1785.

Clinical Significance of Bile Pigment in the Serum.—Meulengracht reports extensive research and experience in two hospitals with colorimetric estimation of the bilirubin in the blood serum. The bilirubin has to reach a certain level in the serum before it passes into the tissues, and a still higher level before it passes into the urine. There are thus two thresholds for bilirubin. The amount of dilution necessary to bring the blood serum to the same tint as that of a 1:10,000 solution of potassium bichromate or a 1:300 solution of ferric chlorid is the colorimeter gage. He draws 3 c.c. of blood into a Wassermann glass containing a few drops of a 20 per cent. solution of sodium citrate. Only 1 c.c. of the serum is taken for the test. The dilution figure may range from 10 or 20, with slight jaundice, to 200 or 300 in the severer cases. Bilirubin is found in the blood as febrile or toxic bilirubinemia, and as congestion, hemolysis or obstruction bilirubinemia. Examination of the blood for bilirubin is thus an important aid in detecting slight degrees of jaundice and thus sustaining the diagnosis of liver disease in dubious cases, especially with cholelithiasis, hemolytic and pernicious anemia and certain cases of insufficiency of the heart. Examination for urobilinuria supplements but cannot take the place of examination for bilirubinemia. He describes in detail and compares the findings in forty healthy persons, and large numbers of others with various forms of liver and heart disease.

THE PATIENT HIMSELF*

HUGH T. PATRICK, M.D.

Emeritus Professor of Nervous and Mental Diseases, Northwestern
University Medical School

CHICAGO

Among the vices of advancing years are carping criticism, garrulity and needless admonition. To all of these I plead guilty and so can only beg your indulgence while I say a few things that I think should be said, knowing that I say them poorly and that I add nothing to our store of knowledge.

My theme is that much neglected individual, the patient himself. Concerning his organs and their functions, we have numberless tomes. Concerning the diseases that attack his parts, we have whole libraries. Concerning the various ways of cutting him open and sewing him up, there are several six-foot shelves. For the manifold instruments, machines and appliances of our armamentarium, an extensive congeries of industries is in constant operation. Indeed, some of us are so used to practicing medicine by machinery that the cortical cell bids fair to shrink into sterile desuetude. But of the patient himself—the man, the woman, the child—relatively little is thought or written.

THE PATIENT ABOVE THE EYEBROWS

What do I mean by the patient himself? I mean what we mean when we speak of our friend, our enemy, our son, our daughter. We like a man because he is sensible, kind or entertaining; dislike him because he is selfish, irritable or pessimistic. So do we admire or despise because of certain mental, not physical, qualities: traits that reside above the eyebrows. Our attitude depends on the individual's personality: the biggest thing to us and to him. It is more important than his kidneys and his liver, and its disorders are as momentous to him and to society as is disease of his organs. His personality is what he is—the man himself; and he is the sum of all his tendencies and experiences; his desires, aversions, affections, hates, passions, inhibitions, appetites, reflections and knowledge. The tendencies are few and simple, the experiences myriad. And a little thought shows that most of this experience has been in the form of conflicts. From the beginning, life is a conflict: an effort to live and be happy—that is to say, an effort to adapt ourselves to the conditions under which we must live. The struggle between what we consciously or unconsciously wish to do, and what the present state of society requires us to do begins in infancy and never

stops. Very early the normal child learns that certain perfectly natural functions may not be fulfilled in a completely natural way. He may not urinate in the parlor nor appropriate anything he happens to see. As we grow older these conflicts become more complex and more acute. Some of us come out of them pretty much to the satisfaction of ourselves and our neighbors. We are the happy, the well and the successful. Some of us are unable to make the adjustment. We, then, are the unhappy, the ill or the unsuccessful. Now, as every one of us has these conflicts and has them all the time, it does not take much perspicacity to see that there are many defeats. Occasionally one comes out of the conflict a thief, a tramp, a pauper, an invalid. Perhaps one does not think of petty larceny, constipation and eye strain in the same terms; but they may be equally due to social inadaptability. Each is the reaction to a difficult situation.

THE RESULTS OF MALADAPTATION

The whole question of health is one of adaptation or adaptability. We have typhoid fever either because individually we are still vulnerable to the typhoid germ, or because as a community we have failed successfully to combat it. Some of us have neuroses or psychoses because we are unable successfully to harmonize with our environment—and for no other reason. Often this fact is overlooked. What has social inadequacy to do with the practice of medicine? A great deal, because it starts a multiplicity of symptoms which the patient expects the physician to relieve. To speak of the hyperacidity and gastric distress of financial insufficiency, the dysmenorrhea of domestic disharmony and the tachycardia of industrial futility may sound incongruous, but sometimes that is what they are.

An easy approach to consideration of the neuroses as a result of maladaptation, that is to say, as the outcome of a conflict, is by way of the war neuroses because there the conflict is so apparent. A war neurosis, grossly misnamed shell shock, is a means of, let us say, getting out of the front line trenches. The soldier can no longer stand the bursting shells, the falling parapets, the horrible sights and the imminent danger of death. But army discipline and morale, personal honor, pride, ideals make running away impossible. A neurosis makes it possible. So does loss of an arm. If he loses an arm, the soldier doesn't have a neurosis. A neurosis is no fun, but it is a great deal better than the trenches.

Peace neuroses are just the same. They are a way out of trouble or around an obstacle; a way selected more or less unconsciously. If one cannot remove an obstacle from his path and cannot surmount it,

* Presidential address, read before the Institute of Medicine of Chicago.

he goes around. Perhaps he *can* push it away, or *can* surmount it; but he *prefers* to go around. For our patients, the way around is often insomnia, "nervous breakdown," backache, dysmenorrhea, asthenopia, indigestion, headache, abdominal pain, dyspareunia, impotence, exhaustion, palpitation and many other things for which medicines are given and operations performed.

As already indicated, a neurosis is by no means the only avenue of escape from an intolerable or uncomfortable situation. Some ways are much simpler. The man who, when tired of his job and dissatisfied with his wife, stops work, gets drunk and beats up his connubial partner, does not develop a neurosis from those particular troubles. He doesn't have to. But he is just the one to get a lame back or sore feet in the army, where he can't escape by the simpler way.

An intelligent and pleasing woman was dissatisfied with her town and her husband. She referred to the former as "a piffing little place," and said of the latter, "He gives me no satisfaction." What was the solution? Recently she spent four months in New York, and with bright eyes and a pleased smile said, "You bet I had satisfaction there." Last winter she visited Los Angeles with the same gratification. Did she have a neurosis? Why should she? There was absolutely no conflict. She was as simple and direct as a child.

Contrast the following:

A woman of 34 years complained of daily headache, poor sleep, ready exhaustion, some dyspnea on exertion, poor appetite and constipation. With considerable pains, I ascertained that she too was dissatisfied with her husband and with her social and financial position. She could not adjust herself to conditions as they were, and she could not change them. Her ideals and training did not allow the simple means of escape adopted by the other. Instead of deliberately going to New York and California, she subconsciously went to headache and insomnia.

NEUROSIS AS DEFENSE REACTION

In short, the neurotic is an individual in trouble with no easy and direct means of escape. A neurosis is a defense reaction, a means of escape; a psychologic dugout in which to hide. That the difficulty may be imaginary, the patient fleeing from a ghost, does not alter the situation. His efforts to adjust his appetites and desires to the demands of convention, society, the herd are the same as ours. He attempts to dodge defeat and to shift responsibility for lack of success as do we whom a lenient society calls normal. Because he played so poorly, an irascible golfer first threw his bag of clubs and then his caddie into the creek. Very, very often the nervously inadequate person unconsciously shifts the responsibility to some bodily trouble, when he naturally comes into the physician's domain. And too, too often the physician takes his complaint at its face value. Sometimes the literalness of physicians is equal to that of religious fanatics. Once I examined a justly celebrated clergyman who was in a state of profound delusional melancholia, in consequence of which he falsely accused himself of sundry grave sins. Having recovered, he was tried by a church tribunal and dismissed from the ministry because of these self accusations of a disordered mind. Such superficiality and narrowness makes a physician smile. But compare the following:

A young man brought to me his wife, who at various medical hands had received sundry powders and potions for insomnia, nervousness and loss of appetite. After a bit of

questioning, I sent the husband on an errand. As the door closed behind him I said, "Now, quick, tell me what's the matter." The startled wife then told me that their young priest, a close friend of the husband, was almost daily assailing her virtue, and that she was quite distracted between fear that she might yield and fear to tell her husband.

And the following:

A woman of 50 years was having a prolonged rest cure because of general nervousness, mental depression, "exhaustion," and insomnia. She appeared to be very weak, and walked across the room with difficulty. A bit of direct questioning revealed that she was intensely afraid of a stroke, and that this fear was based on tinnitus, which she expressed as a "noise in the head." This to her meant cerebral calamity: a stroke, paralysis, death. When the simple situation was explained to her she got up and went to the coast of Maine for a holiday.

Would these medical examples make an ecclesiastic smile? The following incident is not unusual:

Many years ago, only with uncomfortable persistence did I dissuade a well-known surgeon (since deceased) from performing a gastro-enterostomy on his wife. He insisted that she never could be well until operated on. But I knew of grave emotional stress of which he was partly ignorant and which he partly ignored. With the mental adjustment which came about in a couple of years, all abdominal symptoms disappeared, and she has continued well.

How many of us constantly keep in mind that we, the acme of civilization and culture, have every instinct and passion of the caveman? Are we always alert for the ever present emotional-ideational-intellectual conflict? And do we recognize its importance? To repeat: The product of these conflicts is WE—the patient himself. And in the vast and intricate complexity of modern life, the name of the conflicts is legion. Neurotics are just as different as physicians, and for as many different reasons. Consequently, investigation in many directions is necessary. Here laziness, carelessness and false modesty on the part of the physician have no place. I should not like to say, even if I knew, how often to my question "Did you tell all this to all these other doctors?" the reply has been "No, they didn't ask me."

THE SEXUAL ELEMENT

And here I venture a direct word on sex matters. Without following the self-styled psychoanalysts in tracing practically all psychoneuroses to a sexual origin, without even discussing their tenets, I wish definitely to state that something relating to matters sexual has a great deal to do with starting many nervous disorders. Aside from the demonstration of experience, a little reflection will show that this is reasonable. In the present state of society, practically every individual between early childhood and presenility has sexual problems and conflicts. In the solution of the problems and disposition of the conflicts, generally he has the assistance of neither publicity nor knowledge. On the contrary, he is handicapped by ignorance, superstition and isolation. All the conditions are there for the development of fear, shame, remorse, guilt, resentment, a feeling of inadequacy or impotence; the most painful emotions, plus secretiveness. Who would not escape from them by way of a neurosis, very distressing but with none of the tragedy of the other forms of suffering? Thousands of soldiers escaped from the shell torn trenches, that is, from their intolerable

emotions, by way of a psychoneurosis. Millions of us have tried to escape from other tearing emotions by means of so-called functional nervous disorders. Hence, whatever our decision as to the psychology of sex, in the case of the individual patient there is but one answer: sufficient investigation, proper instruction, and counsel based on adequate understanding.

But I do venture to add that, in my opinion, to express love of power, money and ease; fear of pain and death; the satisfaction of food, delights of the eye and ear; the disappointment of failure, the pleasure of work well done, all in terms of sex—howsoever sublimated—is to express a narrow conception of *Homo sapiens*. And I also believe that in the vast majority of cases, the exhaustive and intricate corkscrewing methods of the freudians are unnecessary. Sometimes they are harmful.

DIAGNOSES THAT FALL SHORT

Our medical affinity seems to be the concrete and tangible. Organic abnormality is the most facile explanation of disorder. Given almost any complaint, if the patient reveals undoubted organic disease, our tendency is to stop there. When shall we learn that a prolapsed kidney or stomach may be as good as normal, a valvular lesion innocuous, a urethral stricture of small importance, a deviated septum symptomless, and a torn cervix not even a cosmetic offense? But prolonged fear, disappointment, resentment, anxiety, regret, perplexity are never symptomless. The physician's wife, mentioned above, undoubtedly had enteroptosis; but that did not cause the trouble. The following is a common type:

A middle-aged woman had been operated on for ruptured perineum, rectocele, and "ulcer of the womb"; later, for hemorrhoids and laceration of the cervix. Still later, she had a curettage, and then the ovaries and tubes were taken out. Finally a hernia, a relic of one of the previous operations, was repaired.

No very exhaustive investigation was required to show that this patient never had been physically disabled, but that she always had been intellectually and temperamentally absolutely unequal to life's demands. Each operation was only an additional urge into physical invalidism as an escape from the toil and responsibilities that fell to her lot. That such treatment tends to perpetuate the trouble is obvious. If dysmenorrhea and pelvic pain are really a recourse from laborious housekeeping, ventrifixation fixes the mental attitude of the patient. And the next operation for adhesions makes her more adherent to her disability.

When a woman dates her symptoms from marriage or childbirth, it behooves the physician to look for the presence of discontent, unhappiness and fear. A diagnosis of pelvic disease may have to be changed to mother-in-law, which often means a more or less inadequate daughter-in-law. When a man is disabled by an organic disease or abnormality that apparently doesn't measure up to the disability, one should take the precaution to look for the neurosis which really makes the trouble. A simple arthritis, with which some people would happily limp through life, makes others useless. Why? Because there is something back of the arthritis; something the matter with the patient himself. While the clinical picture may be made up of symptoms strictly organic plus others purely functional, the latter may be by far the more important, even though the former are more salient.

EFFECTS OF FEAR

Elsewhere,¹ I have tried to emphasize the importance of recognizing fear. One might think that if a patient were afraid he would know it and tell of it. Neither may be the case. That one may be sick from fear and not be aware that he is afraid is certainly true. And "to deny fear seems to be almost as instinctive as that emotion itself."¹ That is to say, the physician must not wait for the avowal: he must dig it out. This is especially true of that exceedingly common apprehension, the fear of "losing the mind." Patients will carry this fear for years and never mention it. A very common way of consciously or unconsciously dissembling fear is to complain of the symptom which is the basis or the result of the particular fear. The patient bitterly complains of headache. But the real distress is not the headache (often it isn't a pain at all), but the idea that the headache means insanity or a stroke. Abdominal distress may be trifling, but it is disabling because to the patient it signifies cancer. But he doesn't say so. He hardly knows that it is so. He doesn't wish constantly to be afraid of insanity or cancer; he prefers to have headache or nausea. How can one successfully treat such a headache or stomachache without becoming acquainted with the patient himself?

FREQUENCY OF MILD MELANCHOLIA

One other very practical aspect of the real patient, the patient above the eyebrows, I must at least mention: the frequency of unrecognized mild melancholia. Instinctively, these patients hide their feelings of uselessness and hopelessness, their self reproach and fear of insanity. They complain of what to them seems to be the cause of their ill feeling, and generally this is some bodily complaint. Headache, insomnia, indigestion, constipation, biliousness; exhaustion from overwork, worry or sexual irregularities; leukorrhea, loss of memory and pelvic distress are among the more common. And the literal physician overlooks the disorder of the personality. The result is useless or harmful treatment. This is bad enough. What is worse, the patient is given every chance to commit suicide—which he rather frequently does. In Chicago there are more than 600 suicides a year, and I am quite sure that fully 400 of these are due to melancholia—every one of them preventable.

EFFECT OF DISTURBING EXPERIENCES

The relations of past experience to present conduct are most complex. Our feelings and behavior today are the result of myriad experiences, most of them forgotten, and still more not in our awareness at any given time. No man can trace all the steps that have led him to be a Republican or to dislike a certain person. Why does Miss X delight in ice cream and abominate pork chops? It didn't just happen. There are reasons. Of four men in trouble one prays, one gets drunk, one has a fit and one has a headache. Why? That is for us to find out. Generally it can be done. Not always.

Clinically, the relation of a pathogenic experience to consciousness is generally one of two, with no definite line of division. First, the patient remembers perfectly well the (generally unpleasant) experience, but has no idea that it has anything to do with his

1. Patrick, H. T.: The Factor of Fear in Nervous Cases, J. A. M. A. 67: 180 (July 15) 1916.

present trouble. Second, the disturbing episode has been quite forgotten and is brought back into consciousness only by some unusual stimulus or mental state. Obviously, it may happen that we cannot bring it back at all. To illustrate the first type:

A young traveling man was unable to eat in restaurants because of intense feeling of prostration and oppression, palpitation, etc. He had not in any degree forgotten that a few months before consulting me he had been taken very ill while dining in a restaurant, had nearly fainted and had liberally distributed vomitus over the floor before he could get out. But apparently a connection between the causative disagreeable episode and the neurosis never had occurred to him, and information of the illness was not volunteered. It was elicited by leading questions.

Another example:

A middle-aged, happily married woman complained of nervousness, insomnia, mental depression, intense dislike of social intercourse, even with good friends, and intense agoraphobia. Pains-taking inquiry for more than two hours, evidently with the cooperation of the patient, failed to elicit a cause. Only after the analysis of two dreams by Dr. Lewis J. Pollock, my assistant at that time, did we learn of events in her childhood and youth causing poignant shame and self reproach that were clearly the cause of her disorder. These experiences she had not forgotten; but their relation to her present complaints had never occurred to her, the subject was distasteful, and instinctively, scarcely deliberately, she had suppressed the facts.

An example of the second type:

A young married woman had so-called vaginismus to a degree entirely preventing intercourse. No local cause could be found. The patient neither feared nor objected to the nuptial embrace; indeed, she was most anxious to be a complete wife and an early mother. It was only after many questions and the awakening of many associations that she recalled two not very striking experiences when she was about 11 years old. Aside from temperament, these were the prime cause of her disorder; but apparently for years she had not consciously thought of them.

NEED OF APPROPRIATE TREATMENT

A good many years ago, Möbius described akinesia algera, paralysis from pain; the patient does not move because it hurts to move. When we come to therapeutics for the patient himself, many of us have a sort of amblyopia algera. We do not see because it is uncomfortable to see. It is much more comfortable to say, "nothing to it," "just a nervous crank" and do nothing, than it is to realize that here is a pathologic condition, obscure, maybe complex, that must be laboriously worked out. So we naturally go blind, see nothing and do nothing. Probably every physician makes an effort to regulate the bowels. How many of us make an effort to regulate emotional and intellectual movements? But intestinal stasis is vastly to be preferred to intellectual stagnation: so-called autointoxication is not half so lethal as disintegrating emotions.

To state it another way, we must first have a just conception of the nature of the trouble and then institute *appropriate* treatment. Nowadays few ovaries are removed for dizziness and indigestion, but the "rest cure" is applied about as heedlessly as was formerly oophorectomy. Confinement to bed, isolation, forced feeding and massage for perturbations of the personality may be compared to a linseed poultice for pain in the belly. Occasionally the cataplasm suffices, but treatment of the cause is to be preferred. Equally, we should treat the cause of neurotic manifestations. Who would prescribe a pill for vagrancy or a powder

for prostitution? The tramp and the prostitute are recognized as defective, unadaptable to society as now constituted, except on the underworld level. The psychasthenic (nearly always mis-called neurasthenic), the neurotic, the psychotic is a rather similar product. Unadapted to the upper strata of social efficiency, he gravitates to the underworld level of pain, prostration and dyspepsia: the realm of consultation rooms, hospitals and sanatoriums. But I hasten to add that when properly adjusted to his environment, the neurotic may be one of the most efficient, valuable and delightful members of society.

A fine young woman was about to decline marriage because handicapped, even disabled, by what she did not recognize as phobias. For years she had been unable to go down town except in a carriage, and then only for a few minutes. To go alone to a nearby market was out of the question. Deeply religious, she could not go to church alone, and when accompanied, she could sit only near the exit. There were other phobias. A short course of training and reeducation removed the lot, and for about ten years she has been an ideal wife and mother.

A fine young chap of 22, because hypersensitive and hyper-conscientious, became depressed and worried over the usual sexual problems of youth to the extent of total disability. The situation was explained to him: in a proper environment, he was carefully guided and was gradually led back to normal activities. In the spring of 1917, he entered the army and served brilliantly throughout the war.

An unmarried woman of 29, doing office work, for ten years had had attacks of dyspnea and palpitation, great weakness and insomnia. Although she positively and honestly denied that she was afraid of anything, exact questioning showed that she had several intense phobias. She really was ill and had been for ten years. But the trouble was not the heart muscle, it was lack of adjustment to her job, her associations and necessary conditions of living. Fortunately, she married happily, and her bodily complaints all disappeared.

A woman of 32, of the intellectual type, had been an invalid for years. Accurately to describe her symptoms would require a descriptive catalogue. They included "stomach trouble," "rectal trouble," severe headaches, ready exhaustion, tenderness at places over the abdomen and in the pelvis, loss of weight and anemia. She certainly had enteroptosis, with the right kidney far down. One of the greatest surgeons of Chicago thought it best to take out the appendix, fasten up the kidney, ventrifix and curet the uterus. Did all this help? Not a bit. She was sent East for a prolonged rest cure under the greatest master of that procedure, with the same result. She remained the same practically useless martyr, a burden to herself and the despair of her family. Finally, she was induced to take up an active, intellectual and taxing occupation in an environment that fitted her. Presto! The baffling organic disorders, the profound prostration, the disabling pains evaporated. She had found her place, and she has continued to be a busy, exceedingly useful and happy woman.

The following case shows the obverse mechanism:

A young man of ample means, shy and a bit effeminate, retired to a small farm where he raised a few fancy sheep and experimented in crossing flowers—all to his complete satisfaction, and with perfect health. Circumstances forced him into business and the hated city. He developed rebellious stomach, insomnia and headache, lost considerable weight and frequently his temper.

NATURE OF THE TREATMENT

These illustrations, which might be continued indefinitely and with interesting variations, serve to indicate not only that the neuropath may be useful but also what sort of treatment he should have. Very simply stated, the object is so to mold the patient that he

will fit his environment, and so to arrange the environment or so to place the patient that the environment fits him. Sometimes it cannot be done. Our laws and customs contain fragments from the dark ages and more primitive eras. So do we. Some of us belong to the period about 100 A. D. For such, transplantation to the present epoch is difficult. A few of us belong in the stone age, and we cannot live in the captivity of modern civilization without falling ill. Perhaps occasionally one is 500 years ahead of his time. If so, he has a hard life, and probably is a failure, judged by our standards.

In assisting to adjust a patient to necessary conditions, frequently we have to show him that he can do things that he says he cannot do. That is his way of expressing his great reluctance to do or fear of doing something necessary for his health. Demonstration discounts admonition. He should be given an understanding of his situation; but simply telling him is not enough. We must demonstrate to him that he can eat turnips or walk a mile or sleep without a hypnotic or go without a headache powder.

Let me again emphasize that the headache or the pain in the legs or indigestion is simply a means of escape from something for which the patient feels himself inadequate, or really is inadequate. Our job is to make him equal to the task he is trying to escape or so modify the task that he can perform it, or give him another which he can do with satisfaction. To say, "Don't worry" or "Why Worry?" or "That headache isn't in the least serious" is not enough. The unwholesome ideas, the distressing disorder, can be driven out only by wholesome satisfactory ideas, which in the vast majority of cases means a satisfying occupation, a something which makes life taste good.

THE OUTCOME

And for our encouragement, we may remember that the temperamental individual who is confused and discouraged by life's perplexities and takes refuge in physical disabilities is, when rightly placed, likely to be the finest enthusiast, the most glowing optimist. Just as he is dominated and defeated by a depressing idea, so is he exhilarated and activated by sanguine ideas. Some of the greatest and most beautiful work of all time has been done by these men and women who are too much controlled by their emotions, too sensitive to the jars of a battling society, too unstable to carry the gross burdens of a materialistic world. Ours the task, then to strengthen their intellectual control, to toughen their shrinking sensibilities, and adjust the burden to the bearer. Thus may we, too, add to the sum total of human health, happiness and progress.

25 East Washington Street.

Diet and Health.—A lack of the knowledge of how to adjust income and food expenditures is holding many children back in normal development, and thereby decreasing the ability of future citizens. Oftentimes medicine can be of no lasting value until the diet is regulated, and quite frequently when the diet is regulated medicine is unnecessary; but in the majority of cases the doctor has not the time to sit down and plan this adjustment with the mother, and the problem of food economics is a work apart from nursing, just as nursing is apart from the practice of medicine. To meet just such a situation as this the nutrition specialist in social work has come into existence.—L. L. Gillett, *The Commonwealth* 6:111 (May-June), 1919.

PELVIS OF KIDNEY AS POSSIBLE SOURCE FOR INFECTION OF BLOOD STREAM

PRELIMINARY REPORT *

J. A. H. MAGOUN, JR., M.D.

Fellow in Surgery, Mayo Foundation

ROCHESTER, MINN.

During recent years it has been generally conceded that in cases of renal infection the kidney is infected secondarily following a primary bacteremia. In some instances it seems that the kidney, previously infected either through the blood stream or by an ascending infection, may be the cause from which a bacteremia results. For the purpose of investigating this interesting problem, experiments have been conducted under the direction of the Departments of Urology, of Experimental Bacteriology, and of Experimental Surgery, with reference to the following questions:

1. Can organisms pass from the pelvis of the kidney into the blood stream?

2. Are the conditions under which they pass at all analogous to the pathologic status found clinically?

3. Are there clinical cases in which the kidney has acted as a focus of infection?

Our investigations have been concerned, as yet, only with the first two of these hypothetical questions.

The literature concerning the absorption from or the passage of organisms through the kidney is very meager. Albarran¹ was the first to investigate experimentally the infections of the blood stream through the kidney. In 1888, working with *Bacillus pyogenes*, which was afterward identified as *Bacillus coli* by Krogus, Achard and Renault,² he produced infection in the blood stream by introducing *Bacillus pyogenes* into the ureter. His work was without previous bacteriologic control of the blood, however, and in many cases peritonitis occurred. He traced the organism from the bladder to foci of infection in the kidney. "From these foci the organisms go into the connective tissue and then penetrate into the blood vessels, enter the circulation, and lead to far off emboli." Thus it is seen that thirty years ago the thought was suggested that the kidney might be a focus for blood stream infection.

Burns and Swartz³ do not believe that absorption takes place from the pelvis of the kidney under normal conditions. If an acute pyelitis occurs, however, absorption, and the clinical phenomena of chills and fever result. These authors consider such clinical manifestations as due to the absorption of urine and bacterial toxin either from the blood vessels or lymphatics of the renal pelvic mucosa directly, or from the urine and bacterial toxins retained in the uriniferous tubules. They do not suggest, however, that these clinical symptoms may be due to the passage of the bacteria through the kidney into the blood stream, thus causing a bacteremia. In their later work, after the injection, by the gravity or syringe method, of indigo-carmin and india ink particles into the previously

ligated ureter, they found these substances in the opposite kidney, in the liver, lungs, and spleen. They then conclude: "It is reasonable to suppose that if particles of ink can travel in this manner, bacteria and other foreign substances can do likewise."

Macht⁴ states that certain drugs or poisons may be absorbed through the walls of the ureter and the kidney pelvis. Weld⁵ has shown with what ease certain drugs may be absorbed from the renal pelvis, and the untoward action of some of them. Weld's finding that "absorption from the kidney pelvis indicates that the kidney may be a focus of infection which should always be considered" stimulated me to make the present investigation.

EXPERIMENTAL WORK

Dogs were used in all the experiments. The animals were etherized with a constant ether tension; their condition was kept as near normal as possible by the judicious use of heat, etc. In some of the experiments the blood pressure was recorded. All operative manipulations were carried out with the minimum of trauma and hemorrhage. *Bacillus prodigiosus* was the organism chosen, since it is easily identified, since it

probably never occurs spontaneously in the sites from which cultures were taken, and since it is rarely the cause of bacterial contamination in the laboratory. The bacillus was grown in broth cultures and injected by the gravity method.

A straight glass tube about 2.5 mm. in diameter was connected by a T-tube to a cannula inserted into the ureter and to a graduated buret. The straight glass tube was graduated in cubic millimeters. A stopcock was inserted on each side of the T-tube. The fluid containing the bacteria was placed in the buret and allowed to flow into the graduated tube to any desired height. At this definite and controlled pressure it was then allowed to enter the ureter. Great care was taken to exclude air from the entire system and not to contaminate adjacent tissues.

The dogs were killed with ether at the end of from two to three hours, and cultures taken from the heart's blood, the lungs, liver, spleen, inferior vena cava opposite the renal vein, right kidney cortex and medulla, and left kidney cortex and medulla. The cultures were made by planting from 2 to 5 c.c. of blood and from 0.2 to 0.5 c.c. of the tissue juice of the various

organs into tall tubes of glucose broth. The material from the tissues was obtained by aspirating the macerated particles and juice into sterile pipets. The inoculated tubes were allowed to stand at room temperature for from forty-eight to ninety-six hours. The positive cultures were then plated on plain agar.

SERIES 1.—In the first series, through a lumbar incision a cannula was inserted into the left ureter from 2 to 4 cm. from the pelvis of the kidney. A twenty-four hour broth culture of *Bacillus prodigiosus* was then permitted to flow into the pelvis at from 10 to 30 cm. pressure. From two to three hours afterward the dogs were killed with ether and cultures made as outlined above. Results are shown in Table 1. In twelve experiments even with this low pressure, *Bacillus prodigiosus* was recovered from the blood stream or other organs in three instances. It was found in the left kidney in all but two of the experiments.

SERIES 2.—The procedure in the second series was the same as in the first, with the exception that the pressure at which the organisms were passed into the ureter was increased to from 60 to 78 cm. Results are shown in Table 2. At this pressure, which was slightly less than the secretory pressure of the kidney, the organisms were recovered from the blood stream or other organs in six of seven experiments, and they were recovered from the left kidney in all.

SERIES 3.—In the third series in addition to the procedure followed in Series 1 and 2, a cannula was inserted into the right ureter 4 cm. above the bladder; to the cannula was attached a straight glass tube. The cannula inserted into the left ureter was also 4 cm. above the bladder. A forty-eight hour broth culture of *Bacillus prodigiosus* and washings from forty-eight hour agar slants were placed in the buret and allowed to flow into the left ureter, while the pressure was

kept under 21 cm. The tubing connected with the cannula in the left ureter was then clamped. The femoral vein was isolated, and from 100 to 150 c.c. of a 5 per cent. sodium sulphate solution were injected slowly. The secretory pressure of the right kidney was measured in the graduated tube connected with the right ureter. After from two to three hours the routine procedure as previously described was carried out. The organisms were introduced under a very low pressure and the intrapelvic pressure was subsequently increased by stimulation of the kidney. The results are shown in Table 3. In four of these five experiments, *Bacillus prodigiosus* was recovered in other organs than the kidney.

It may be concluded, therefore, that bacteria can pass from the kidney pelvis into the blood stream, and that they may do this under conditions analogous to some of the pathologic states found in man.

INTRAVENOUS INJECTIONS OF HYPERTONIC GLUCOSE SOLUTION IN INFLUENZAL PNEUMONIA

CLIFFORD W. WELLS, M.D.

Captain, M. C., U. S. Army

DES MOINES, IOWA

AND

R. C. BLANKINSHIP, M.D.

Lieutenant, M. C., U. S. Army

MADISON, WIS.

One of the trying experiences of the medical profession during the late pandemic of influenza was the apparent helplessness in the treatment of the chief complication, pneumonia. The experience at the Camp Travis Base Hospital probably paralleled that of other similar institutions. At first, only the commonly accepted methods of treatment were used; but it soon became evident that some additional measures must be employed, else a very high mortality would result. At this hospital, resort was made to the use of quinin because of its recognized pneumococcal action, and to the intravenous injections of hypertonic glucose solution. The results following the quinin medication are to be reported by others. The good results following the glucose treatment are attested by a relatively low mortality. This report deals with the results obtained in 319 cases of influenzal pneumonia, in which one or more injections of a sterile hypertonic glucose solution were used.

The use of glucose in the treatment of serious diseases is not new: heretofore, its use has been restricted chiefly to administration by mouth and rectum for the purpose of supplying the organism with a food easily assimilated and of high caloric value. Litchfield¹ has recently urged the intravenous use of hypertonic glucose solution in serious diseases. The present report is offered because it comprises the largest series of cases on record in which the intravenous use of a hypertonic glucose solution has been intensively employed in the treatment of pneumonia.

PREPARATION OF SOLUTION AND TECHNIC OF INJECTION

The solutions were prepared in the base hospital laboratory from chemically pure glucose: Several thousand cubic centimeters of a solution of a desired strength were prepared in distilled water brought

slowly to the boiling point in order to dissolve the glucose, and filtered through a heavy layer of cotton to remove any gross contamination; then they were made up to the original volume, autoclaved at 20 pounds pressure for twenty minutes, again filtered through several layers of filter paper and made up to the original volume with distilled water, after which the solution was distributed into suitable flasks, holding about 300 c.c. These flasks after being properly stoppered were again autoclaved, and set aside for use as needed. The necessity for several filtrations is important, for in our experience, the boiling as well as the autoclaving tended to precipitate foreign matter which otherwise would be injected. We have used solutions of four strengths in this series: 5, 10, 15 and 25 per cent. strengths of glucose.

The technic of injection and the apparatus are those commonly employed in the intravenous injection of arspenamin. Any large vein is suitable for puncture, usually one in the antecubital space being selected. Only three precautions should be taken: First, the solution, containers, tubing and needles should be sterile. Second, the solution as it enters the vein should be kept slightly above body temperature; this may be accomplished by placing the rubber tubing in a basin of warm water. Third, the solution should be injected slowly; it should require from thirty to forty minutes to complete the injection of from 250 to 300 c.c. We have found that if the fluid is allowed to flow from the needle before puncture at the rate of from sixty to ninety drops per minute this precaution will have been taken. A pinch-cock attached to the rubber tubing is used to control the rate of flow.

RESULTS IN THREE GROUPS OF CASES

For the purpose of comparison, the cases in this series are divided into three groups, based on as accurate a prognosis as possible at the time of the injection. Group 1 includes those patients who were seriously ill, but who were expected to do reasonably well under the usual methods of treatment. Group 2 includes those patients who were critically ill, but who had a fighting chance for recovery under the ordinary methods of treatment. Group 3 includes those patients

TABLE 1.—RESULTS OBTAINED IN A SERIES OF THREE HUNDRED AND NINETEEN CASES

who invariably died under the former methods of treatment. Many of the patients in the latter group did not receive glucose injections until late, other methods being tried first, only to fail; many were practically moribund at the time of the first injection, as will be noted in the illustrative cases. The subdivision of each group into A and B denotes the day of the disease on which the injections were given. In Group A the injections were made on the first, second or third day of the disease; while Group B includes patients in whom injections were made after the third day. Table 1 shows the results obtained in 319 cases, as regards mortality and length of febrile period.

1. Litchfield, Lawrence: Glucose Intravenously as a Therapeutic Measure, J. A. M. A. 71: 503 (Aug. 17) 1918.

So-called protein reactions occurred in forty-two cases. Possibly the complete removal of all foreign material from the solution would eliminate this feature. Table 2 shows the mortality rate as regards strength of solution injected. The distribution of the forty cases as regards strength of glucose injected is shown in Table 3.

The subjoined case reports illustrate the effect of the glucose injections. The first case was one of the most severe encountered during the epidemic, while the second was quite severe but less so than the first.

REPORT OF CASES

CASE 1.—The onset of influenza occurred, Oct. 29, 1918, and of pneumonia, Nov. 3, 1918. The patient was admitted to the hospital, November 2. The day following, bilateral consolidation of the lower lobes was noted. November 4, 250 c.c. of a 10 per cent. glucose solution were injected intravenously. November 5, the condition was critical, the patient was semi-comatose and delirious, and there were marked cyanosis and dyspnea. Two hundred and fifty c.c. of the glucose solution were given which produced some improvement in the degree of cyanosis and in the condition of the pulse. November 6, the lung involvement had extended to the left upper lobe; the pulse was rapid and weak; the temperature was 103.8 F.; the pulse rate was 120, and respiration was 38. Two hundred and fifty c.c. of glucose solution were injected, after which the pulse became stronger and slower. November 7, the pulse rate was 130 and was irregular. Two hundred and fifty c.c. of glucose solution were injected. The patient was delirious, but slept after the injection, the first time in three days. November 8, the pulse was rapid and thready, respiration was shallow, the nails and lips were extremely cyanotic, and the mouth and tongue were dry and coated. Two hundred and fifty c.c. of glucose solution were given intravenously, after which the patient slept. November 9, the patient was still delirious and cyanotic. Two hundred and fifty c.c. of glucose solution were injected, followed by marked improvement. November 10, the patient was rational, there was no cyanosis; the pulse was regular, and of improved quality. The patient continued to improve, but convalescence was prolonged owing to the development of pulmonary tuberculosis.

CASE 2.—The onset of influenza occurred, November 7, and of pneumonia, Nov. 11, 1918. The patient was admitted to the hospital on the latter date with definite consolidation of the right lower lobe, and with temperature of 103 F. November 15, the lung involvement had extended to the right middle lobe, and the patient became extremely cyanotic and dyspneic. He was given 250 c.c. of a 10 per cent. glucose solution intravenously, which was followed by a moderately severe reaction, after which he showed remarkable improvement. The following day he had improved, but he was given a second injection of glucose. November 18, the temperature was normal, and recovery followed.

COMMENT

The beneficial effects of an intravenous injection of glucose solution are most striking in those patients who are critically ill, and who present the toxic symptoms commonly observed in this disease, as nausea and vomiting, anxiety, restlessness, vasomotor disturbances shown by cyanosis, rapid, feeble pulse, a cold, clammy skin, and a dry coated tongue and mouth. In many instances, a change occurring shortly after the injection to a state of well being seemed almost miraculous. Frequently, the patient would fall into a restful sleep before the completion of the injection.

An analysis of Table 1 shows that among 112 patients in Group 1 there were no deaths; among 124 patients in Group 2 there occurred eight deaths, and among eighty-three patients in Group 3 there occurred fifty-four deaths. The mortality rates for each group being: Group 1, 0; Group 2, 6.45, and Group 3, 65.06. It is expected that the mortality would be lower among those patients receiving glucose early, yet in Group 2 there occurred eight deaths among eighty-seven patients receiving glucose injections during the first three days of the disease, while among thirty-seven patients to whom the injections were not given until after the third day there were no deaths. The number of cases as well as the number of deaths in this group is too small to warrant the drawing of any conclusions from these results. In Group 3 there occurred thirty-four deaths among fifty-one patients receiving injections during the first three days of the disease, while among thirty-two patients receiving the first injection after the third day there occurred twenty deaths, the death rate being slightly lower in the latter. Two points must be considered before any conclusions are drawn in regard to Group 3 cases; first, that a hopeless prognosis had been made in all these cases; and second, that by the end of the third day some of the patients in Subgroup B had probably developed a certain amount of immunity. Quite significant is a definite shortening of the febrile period in those cases in which glucose was received prior to the third day; in each group, this time was reduced practically 50 per cent. Complications were too few to warrant the drawing of any conclusions relative to the influence of glucose injections on their occurrence.

The majority of patients in this series received injections of a 10 per cent. glucose solution. The important facts relative to the relationship of different strengths of the solution injected to the number of deaths are shown in Table 2. The lowest death rate occurred among those patients receiving a 15 per cent. solution, and the highest among those receiving a 5 and 25 per cent. solution. The number of cases in these three series differs so slightly that the inference that a 15 per cent. solution is the one of choice is probably not warranted. The death rate in the group of cases in which the 10 per cent. solution was used is 19.4 per cent., the average for the entire series of 319 cases being 19.1 per cent. From our experiences we have not been able to demonstrate that the injection of a 25 per cent. solution has any particular advantage over that of a 10 per cent. solution. Theoretically a 25 per cent. solution should be more efficacious than a weaker solution, and possibly its use in a larger series of cases than ours would bring out this advantage.

PROTEIN REACTION

The occurrence of the so-called "protein reaction" following the injection of glucose solution is mentioned

by Litchfield; we encountered it in forty-two instances, or 13.4 per cent., of the patients injected. Erlanger and Woodyatt,² and Wilder and Sansum³ have given a large number of glucose injections without the occurrence of such reactions. Concerning what may be the responsible factor for this phenomenon we confess ignorance. It has been suggested that failure to remove all foreign matter from the solution may be responsible. Opposed to this suggestion is a condition that we have several times observed: In attempting to provoke a therapeutic protein reaction, we have repeatedly failed after the addition of 1 c.c. of our killed typhoid bacilli mixture to 250 c.c. of glucose solution, and this occurred in patients who previously and afterward showed a typical reaction following the injection of the same amount of the bacterial mixture diluted in 2 c.c. of physiologic sodium chlorid solution. We are certain no harm has resulted in our cases from the occurrence of this reaction, and, as reported elsewhere,⁴ it may have a definite therapeutic value.

ACTION OF GLUCOSE

The mechanism by which glucose solution aids in recovery is somewhat complicated and probably not altogether known; undoubtedly both the ingredients present in the solution play a definite rôle. Litchfield has emphasized that the process of dehydration in serious diseases is especially potent for evil because least appreciated and consequently neglected in treatment. The introduction of several hundred cubic centimeters of water directly into the blood stream immediately tends to correct this dehydration. The introduction of hypertonic solution into the blood stream would render the blood hypertonic if it were not for several changes which occur to maintain a state of isotonicity. The value of the glucose solution lies in part in the occurrence of these changes. As the glucose solution enters the blood, there at first is a withdrawal of fluids from the body tissues sufficient to maintain an isotonic condition in the blood. That this is probably the case is shown by the fall in the hemoglobin content of the blood following such injections; and also blood chemistry studies, in our cases, of blood taken during and shortly following the injections show a normal sugar content. The latter finding may possibly be due to a withdrawal of the glucose from the blood as rapidly as it is injected; but it may also mean a dilution of the blood by fluids extracted from the tissues of the body. This condition is not due to the elimination of glucose from the body through the kidneys for in our cases glycosuria was uniformly absent. The occurrence of the extraction of fluids from the tissues, as just assumed, would only tend to increase the degree of dehydration in the tissues of the body, if it were not for the fact that the glucose is rapidly taken up by the tissues. This process is increased by the condition of starvation present in the tissues, and makes demand on the blood for fluid which is necessary in the physiologic process of cell metabolism; this brings about a reversible flow of fluids to the tissues, and tends to neutralize the tissue dehydration.

In diseases characterized by toxin production, either from the products of the infecting organisms or from the products of catabolism, with the extraction of fluids

from the tissues there is considerable washing out of toxins into the blood stream, from which these may be more readily eliminated through the kidneys.

In addition to the influence of the glucose solution on the condition of dehydration, it also has a marked effect on the condition of starvation, characteristic of most serious infectious diseases. Lusk⁵ has pointed out that there is a certain amount of stimulation of cell activity by glucose, in addition to its purely food value. The marked improvement in the pulse following glucose injections would suggest a possible direct stimulation of the cardiac muscle.

We do not know how to account for the marked improvement in desperate cases following glucose injections, unless they are due to the theoretical processes that have just been mentioned. One is struck by the rapid improvement in many cases: patients previously restless and semidelirious have dropped into a restful sleep during the course of an injection, the anxious toxic look has disappeared, and the hot, dry skin has become moist. The tongue, previously dry and coated, has become moist. The appetite for food and liquids becomes less capricious and is stimulated. The urinary output is increased.

CONCLUSIONS

1. The intravenous injection of glucose solution is a valuable aid in the treatment of serious cases of pneumonia.
2. The results following are almost immediate, but are not necessarily lasting; and success may follow only after repeated injections.
3. The injection of glucose solution is not more difficult than the injections of other intravenous medication.
4. It is not intended that glucose solution should be substituted for antipneumococcic serum in cases of Type I infections; it may, however, be added to the serum treatment.

AN OUTBREAK OF BOTULISM

REPORT OF CASES

CHARLES G. JENNINGS, M.D.

ERNEST W. HAASS, M.D.

AND

ALPHEUS F. JENNINGS, M.D.

DETROIT

The outbreak of *Bacillus botulinus* poisoning reported in this paper occurred at Grosse Pointe, a residential suburb of Detroit. The source of the toxin was a glass jar of ripe olives. This food was later analyzed by Dr. Herbert W. Emerson of the Hygienic Laboratory of the University of Michigan, Dr. Plinn F. Morse of Harper Hospital, and the Detroit Board of Health. *Bacillus botulinus* was found by each of these investigators, and the fluid from the olives was demonstrated to be lethal for guinea-pigs in doses of 0.01 c.c.

THE OUTBREAK

The olives were first served at a formal dinner, Oct. 18, 1919, at the residence of Mr. M. W. S., and there were present the host, hostess and six guests. One of the guests noticed that the olives were soft and remarked that they had a peculiar odor. They were, however, eaten by four of the diners and one waitress, and of this group two died, two were made moderately

sick but recovered, while one escaped entirely. On the following days, October 19-21, the olives were eaten by Master L. S. and Miss F. S., children of the host, and by Miss J. M., a waitress in the home. All of this group died. There were in all eight persons who are known to have eaten the olives. Of these one escaped entirely, two were slightly affected, and five died.

CLINICAL HISTORIES

CASE 1.—Mrs. C., aged 27, a temporary waitress, ate two or more olives in the evening after the dinner. On the morning of the next day, October 19, she had slight difficulty of vision, pain in the head and nervousness. At noon she had slight difficulty in swallowing. She was seen by her family physician about 3 p. m., who could find no objective symptoms of disease. At 7 p. m. she began vomiting and had moderate abdominal pain and diarrhea. These symptoms soon were followed by collapse, and death occurred at 10 p. m., twenty-four hours after eating the fruit, and twelve hours after the onset of symptoms.

CASE 2.—Mr. A. I. L., aged 45, ate one or more olives at dinner, October 18. The following day, October 19, he played golf. While on the links he had difficulty of vision, and on returning home he said that he had never felt so tired before. October 20, he noticed diplopia and at night difficulty in articulation. October 21, he developed great difficulty in swallowing and articulation, which later developed into total paralysis of deglutition and phonation. At this time the pupils were dilated and reacted slowly to light. There was internal strabismus of the right eye and partial ptosis of the right eyelid. The eyes were suffused and red. There was paresis of the whole right face. The pharynx and larynx were filled with thick mucus, which the patient could not dislodge. The blood pressure was 140 systolic and 80 diastolic. There was no fever, the urine was normal, the nonprotein blood nitrogen was 36 mg. per hundred c.c., and the Wassermann test was negative.

October 22, dyspnea with laryngeal spasm began. The tongue could not be protruded. The patient became weaker and died of respiratory paralysis that evening, four days after taking the toxin and after an illness of three days.

CASE 3.—Mrs. A. I. L., aged 43, ate a small part of one olive at dinner, October 18. October 21, about sixty-five hours following the meal, she developed slightly disturbed vision, mild ptosis, obstinate constipation and difficulty in swallowing solid food. These symptoms were not severe, and she recovered in a few days.

CASE 4.—Mrs. M. W. S., aged 48, ate a small part of an olive, October 18, and a whole olive, October 19. October 22, she noted mild haziness of vision with diplopia, and October 23 slight difficulty in swallowing solid food, and moderate ptosis of the right eyelid. Aside from the ptosis the physical examination was negative. October 24, at 8 p. m., she received 1 c.c. of antitoxin serum intravenously and 10 c.c. at 9 p. m. On the following day she received 10 c.c. subcutaneously. The ptosis continued for several days, and she recovered very slowly from the nervous and muscular debility.

CASE 5.—Master L. S., aged 12, ate an unknown number of olives, October 19, 20 and 21. October 22, about noon, he vomited once and then was comfortable until late in the afternoon, when he developed dimness of vision and diplopia and had difficulty in entering his home from the automobile. About 7 p. m. he began vomiting, and about 8:30 p. m. he had a severe convulsion lasting one minute. He vomited once after the convulsion. At this time there began inability to swallow and speak and marked weakness. He rapidly failed, and died of respiratory paralysis at 3 a. m., October 23, three days after first eating the olives and twelve hours after the onset of symptoms.

CASE 6.—Miss J. M., aged 43, a maid in the home of Mr. M. W. S., ate an unknown number of olives, October 19-21. About 3 p. m., October 22, she began vomiting, with moderate abdominal pain. During the afternoon she developed difficulty in swallowing, diplopia and dimness of vision. These symptoms kept up for twenty-four hours, but she had several

periods of a few hours each during which they cleared up almost completely. Calomel was given and good catharsis obtained. She found that olives relieved her nausea and so kept on eating them. On the morning of October 23 she vomited blood. At noon of October 23, paralysis of deglutition became complete and ptosis of the left eyelid was present. During the afternoon she became very weak and had difficulty in breathing, it being necessary to use all the accessory muscles of respiration. The pharynx was filled with thick mucus. In the evening she was in a semicomma and the pulse was rapid, weak and irregular. Nystagmus and strabismus were observed, and râles were present at the bases of both lungs. She died of cardiac and respiratory paralysis at 10:30 p. m. on the fourth day after eating olives, and about thirty-six hours after the onset of symptoms.

CASE 7.—Miss F. S., aged 23, ate a total of two or more olives, October 19-21. Illness began on the morning of October 22, when she noticed coryza and sore throat, blurred vision and diplopia. She did not feel sick. October 23, she felt weak. About noon, she started to eat soup and was unable to swallow it. She became nauseated and vomited once. Because of weakness and dimness of vision, she had to be assisted to bed.

At this time the heart, lungs, abdomen and general examination were negative. There was ptosis of both eyes, so that the patient had to throw back the head to see. There was paralysis of the right external rectus muscle. The pupils reacted to light and accommodation, and were normal in size. There was no paralysis of the facial muscles, and the tongue protruded normally. The patient was unable to swallow food or liquids, and there was an accumulation of thick mucus in the pharynx which she could neither expel nor swallow. Her mentality was clear, there were no paralyses or disturbances of sensation, and the deep reflexes were normal. The urine was normal. During the night she rested well.

The following day, October 24, the patient was weaker, but the ptosis was less. Other signs were unchanged, and she spent a comfortable morning. At noon she complained of smothering, and the respiration became wholly thoracic and labored with the accessory respiratory muscles in play. There was no cyanosis or dyspnea. The mucus became more annoying. With difficulty of respiration, the mentality became more anxious and the patient restless. The physical signs did not change during the day.

In the morning the duodenal tube was passed easily to the stomach. Two ounces of magnesium sulphate in one pint of water were injected and later, before the tube was removed, 8 ounces of milk and two eggs. There was a good bowel movement after five hours, and the patient passed about 15 ounces of urine during the day.

At 4:40 p. m., 10 c.c. of antitoxin serum were given intravenously. At 5:45 p. m., 20 c.c. were given, and at 2:15 a. m. of October 25, 12 c.c. There was no reaction, and the injections seemed to quiet the patient.

On the final day, October 25, she was clear mentally, but drowsy and almost too weak to move. Speech, which up to now had been fairly clear, became very indistinct. The tongue could not be protruded. She complained of numbness in both hands and kept rubbing them "to restore the circulation." She suddenly became cloudy mentally, and the pulse rose to 160. In a few moments she became comatose, the pulse and respiration became slow, and she died of respiratory paralysis seventy-two hours after her first symptoms and on the sixth day after first partaking of the olives.

ANALYSIS OF CASES

Onset.—Difficulty of vision was the first symptom in five cases, and vomiting in two. Abdominal pain was present with the vomiting in one case, and weakness was an accompanying symptom in two cases, in one of which it was very severe. The symptoms began within twelve hours in one case, twenty-four hours in one case, sixty hours in one case, and seventy hours in four cases. The onset was gradual, and in only one case was it of such a character as to cause apprehension of illness on the part of the patient.

Course.—Once established, the disease became steadily and progressively worse in the fatal cases, excepting the one in which the patient showed some temporary relief for a few hours at a time. Death occurred in twelve hours in two cases, thirty-six hours in one, and seventy-two hours in two.

Gastro-Intestinal Symptoms.—These consisted of vomiting and moderate general abdominal pain. They dominated the clinical picture in Case 6, and masked the neurologic syndrome in Cases 1 and 5. They were absent or negligible in the remaining four cases. It was observed that death occurred much more quickly in the patients showing gastric symptoms, and that so far as could be determined they ate more of the poisoned food than did the patients showing only neurologic symptoms.

Neurologic Symptoms.—With the exception of paralysis of the diaphragm, the motor lesions were confined to the cranial nerves.

The olfactory (first), the trigeminal (fifth) and the auditory (eighth) nerves were not affected in any of the cases. The oculomotor (third), the trochlear (fourth) and the abducens (sixth) nerves were involved very early in every case. There was ptosis of one or both eyelids, and diplopia and paralysis of one of the ocular muscles, in two of the cases the right external rectus being affected. In only one of the cases, Case 2, was mydriasis present. Nystagmus was observed in Case 6. Vertigo was not seriously complained of by any of the patients. The facial (seventh) nerve showed involvement in Case 2, in which paresis of the right face appeared. The paralyses involving the glossopharyngeal (ninth) and the vagus nerves (tenth) were the most distressing features of the illness and occurred in every case. The difficulty of swallowing appeared shortly after the disturbances of vision, and sooner or later complete paralysis ensued. Strangling generally followed attempts to swallow. Though there was no excess of secretion, there was an annoying accumulation of mucus in the pharynx and larynx which the patient could not expel. There was great difficulty in articulation in Case 2. Paralysis of the trapezius and sternocleidomastoid muscles or of the deep muscles of the neck was not observed. The spinal accessory (eleventh) nerve may have been involved in the pharyngeal paralysis. Paralysis of the hypoglossal (twelfth) nerve appeared in two cases shortly before death. Paralysis of the diaphragm, as evidenced by total absence of abdominal breathing, was observed in Cases 6 and 7 toward the end of the illness. It may have been overlooked in the others. The patients at that time breathed heavily but not over 28 per minute, and the accessory respiratory muscles were in play. They complained of smothering and lack of air, but there was no cyanosis of lips or face. Whether the paralysis was due to injury to the phrenic nerve or to interference with the respiratory center we are unable to say. Incoordination was not observed.

A general convulsion occurred in Case 5 (Master L. S., aged 12). It was severe but of short duration, and did not recur.

With one exception, the mentality was clear in all the patients until shortly before death, when drowsiness and inattention to environment appeared. Patient 6 had a period of coma on the last day lasting two or three hours from which she partially aroused. Patient 1, not observed by us, was described by her physician as hysterical, which condition was

attributed to a domestic misunderstanding of a few hours before.

The temperature was normal or subnormal in all cases except following serum administration in Case 7 and shortly before death in Case 2. The respiration was below 30 in all cases in which it was noted. The pulse was rapid and variable in rate, a little exertion or anxiety sending it as high as from 130 to 150 per minute. The general physical examination was negative in all cases except Case 6, in which there were râles at the bases of the lungs a few hours before death.

Urinalysis in two cases was negative. Blood counts were not made. One nurse called our attention to a peculiar sweetish odor in the stool of three patients.

The termination of illness came with great weakness and collapse, slowing and diminishing of the respiratory excursion, and a rapid, weak pulse. The heart continued to beat after the breathing had ceased.

Diagnosis.—In our experience, two points stand out: First, cranial nerve paralyses are constant symptoms in food poisoning due to *Bacillus botulinus*; they frequently precede the gastric symptoms, and they may constitute the whole clinical syndrome. Second, the time of onset of symptoms varies to such an extent that the poisoned individuals may become widely scattered and the presence of an outbreak may not be recognized.

The first patient to be taken sick, Case 1, was not observed by us and her illness was unknown to the family until, seeing the report of the death of the boy in the papers, her relatives called up. Her physician was puzzled over the case and suggested poisoning, but his suspicions were not aroused enough to demand a necropsy.

The cause of illness in the second patient was also unrecognized. A diagnosis of pseudobulbar paralysis was made on the evidence of paralysis of the third, seventh, tenth and twelfth cranial nerves, the first two showing right sided lesions. The etiology of the condition was obscure because the patient was in excellent health and presented no evidences of cardiovascular disease or syphilis. A bulbar palsy of infectious origin was ruled out by the absence of fever, and similarly a diagnosis of acute poliomyelitis with bulbar symptoms was discarded. Because of the rapidity of the course, progressive muscular atrophy of the bulbar type and myasthenia gravis were not considered. Poisoning by belladonna, hyoscyamus or gelsemium were impossible because the patient had not taken any of the drugs. The unsatisfactory conclusion was finally reached that cerebral thrombosis and softening were responsible for the condition. When, October 22, the boy and the maid in the home of Mr. M. W. S. came down almost simultaneously with gastro-intestinal and neurologic symptoms, the presence of food poisoning was recognized and the diagnosis of the two previous cases was cleared up.

Treatment.—Antibotulinus serum was obtained through the kindness of Prof. Robert Graham, of the University of Illinois. Forty-two c.c. of the serum were administered intravenously in Case 7, forty-eight hours after the initial symptoms. It did not affect the disease. Patient 4 received 10 c.c. of antiserum intravenously forty-eight hours after the initial symptoms, and twelve hours later 10 c.c. were given subcutaneously. Her illness was very mild, and we cannot state that the serum had any influence on her recovery.

To be of value, the serum must be administered early. This can be accomplished only by an early recognition of the disease and by having depots of serum

in various centers about the country. The dosage has not been fully established. McCaskey used small amounts, while Dickson reports the use of 85 c.c., or about 250,000 units. If a case of botulism occurs, careful search for the poisoned food should be made and all persons who have eaten it should be given good sized prophylactic doses of the serum.

Gastric lavage, free catharsis by castor oil and enemas, sedatives, supportive measures and, in the subacute cases, feeding by the stomach tube are indicated.

REVIEW OF THE LITERATURE

Dickson¹ states that up to October, 1918, there had been thirty reported outbreaks of botulism in the United States, with 104 cases and seventy-three deaths. Besides these he mentions four unreported outbreaks with a total of twelve cases and two deaths. Bine² reports an outbreak of three cases and two deaths, Nevin³ one of three deaths, and McCaskey⁴ one of seven cases and four fatalities. During the past year, besides the outbreak observed by us, one has been reported by Thom, Edmondson and Giltner,⁵ and a third occurred in Ohio recently. Thom's outbreak was of five cases with four deaths, and the one in Ohio of eight cases and six deaths. There have been, therefore, at least forty recognized outbreaks of botulism in the United States, with 150 cases and ninety-seven deaths.

The pathology of the disease has been studied by Dickman. The abdominal and thoracic viscera show congestion. The veins and in some cases the arteries show varying degrees of thrombosis, the process beginning in the endothelial lining and eventually leading to occlusion. In the nervous system there are vascular congestion and hemorrhages, more marked at the base of the brain and in the region of the pons. Microscopic changes in the nuclei of the affected nerves were not found by Dickman. He is unable to explain the pathogenesis of the paralyses. We have found no record of examination of the peripheral nerves.

The clinical findings in the recorded cases have been similar to ours. The onset generally occurred before or on the third day after ingestion of the poison, though delays of six and nine days have occurred. The paralyses of the third, fourth, sixth and tenth cranial nerves were almost universally present. Great muscular weakness, incoordination and staggering were often found. Several persons have had paralysis of the sternocleidomastoid and trapezius muscles. Motor paralysis of the stomach with food retention for many days has been noted, and severe constipation is common. The course of some of the cases has been longer than ours, and there are several instances in which patients extremely ill eventually recovered after weeks of illness. The laboratory tests were all negative except for moderate leukocytosis.

Burke⁶ has demonstrated that *Bacillus botulinus* occurs in nature under conditions that are ideal for the contamination of foods such as are canned for human consumption. In certain regions she has recovered the organism from moldy and bird picked cherries, pole bean leaves, spiders taken from bean plants, and moldy

hay. It was also found in the intestinal contents of a hog that had eaten vegetables contaminated by the bacillus several months previously. Burke⁷ has also found that the spores are more resistant to heat than has previously been supposed, some of them surviving a temperature of 100 C. for from fifteen minutes to two hours, and steam under 15 pounds pressure for ten minutes. Dickson, Burke and Ward⁸ have investigated the efficiency of certain of the methods for sterilization of home canned vegetables. They found that the organism survived when the can was placed in boiling water for two hours, and when fractional sterilization of fifteen minutes for three successive days was employed. Fractional sterilization of one hour for three successive days, provided the cans were tightly sealed during the interval, was successful in sterilizing the food, as was the method of adding over 2 per cent. lemon juice to the food and exposing the cans to boiling water for one hour. The toxin is destroyed by light and air, but maintains its virulence for more than six months if it is sealed and in a dark place. It is not destroyed by the gastric juice. It is destroyed by a temperature of 80 C. for half an hour and by boiling.

A REVOLUTION IN TREATMENT OF CONGENITAL DISLOCATION OF HIP IN YOUNG CHILDREN

HENRY W. FRAUENTHAL, A.C., M.D.

Physician and Surgeon-in-Chief, Hospital for Deformities and
Joint Diseases
NEW YORK

The method for the correction of congenital dislocation of the hip has been in vogue only about twenty years, and up to the time of the innovation which I shall describe, the correction has been done either by the closed method after the style of Lorenz, or by the open method as devised by Hoffa in recalcitrant cases. Both of these methods require a long period of encasement in plaster of Paris, followed by corrective exercises, the duration of the treatment extending over a period of many months.

Chance has placed in my hands a method which has been successfully applied to twenty-five cases and which I wish to present to the profession, this method being used in children up to the age of 2½ years.

In reviewing the literature of the anatomy of congenital dislocation of the hip, we find, according to Drs. S. S. Davis,¹ John Ridlon² and Ralph Thompson³, that before the child has borne weight on the affected limb, the head and the acetabulum are normal and there has been no muscular contraction. It is only after the weight has been borne on the affected limb that the muscles about the hip joint are contracted, the upper dislocation resulting in a stretching of the ligamentum teres; and ultimately the artery accompanying the ligamentum teres fails to functionate, resulting in a malformation of the head of the femur.

2. Ridlon, John: N. Y. Acad. of Medicine, March 3, 1904.

3. Thompson, Ralph: Lancet **2**:777, 1909.

The origin of the method here described dates back to Oct. 17, 1918, when, in the presence of a number of visiting physicians, I replaced, without an anesthetic, a hip that was congenitally dislocated, in a child, aged 2 years. Wishing to demonstrate to one of the visiting surgeons present the simplicity of the replacement of the hip without an anesthetic, I attempted to displace the hip again; but, having failed to do so after a ten minutes' effort, I said I would permit the child to go about without applying the usual plaster-of-Paris fixation and allow the dislocation of the hip to reoccur, so that the following week I might give the visiting surgeon the opportunity of performing the replacement without an anesthetic as I had done. When the child returned, the following week, our surprise was great to see that the head of the femur was fixed firmly in the acetabulum. I was so impressed with this unexpected result that I have attempted this method on all young children with congenital dislocation of the hip, coming under my observation when they first begin to walk. I have so operated on twenty-five patients in the past year, making the correction without an anesthetic.

Of these twenty-five patients operated on, I myself was compelled to place in plaster of Paris one limb that would not remain in the acetabulum, and I know of only one other such case, in which the cast was applied at another institution.

TECHNIC

The pelvis is held fixed by an assistant; the thigh is completely flexed on the abdomen; pressure is made on the knee which brings the head of the femur under the acetabulum, and as the leg is rotated outward in the flexed position, the head of the femur is raised into the acetabulum, with the fingers of the other hand. The whole procedure in these cases is accomplished in less than a minute's time. The child is immediately placed on the ground and allowed to walk; and in one case, a child, aged 2 years, walked seven blocks on leaving the dispensary, immediately following the operation.

It is my intent to make a detailed report of these cases in about a year, at which time roentgenograms will be presented showing the dislocation and the replacement of the hip, and photographs showing the apparent shortening and cure. Sufficient time will have elapsed then to appreciate what percentage of perfect cures can be accomplished by this new method.

The method is not adapted to children that have walked on the affected limb for six months or more: then the old Lorenz method must be resorted to. It is effectual only when the child first starts to walk; and the oldest patient in whom I have been able to make the correction effectually was 2½ years of age.

A number of these cases were reviewed by the fellows of the American College of Surgeons during the recent October meeting.

CONCLUSIONS

From the observations of Thompson, Davis and other anatomists, one may conclude that:

1. Before the child bears weight and develops muscular and ligamentous contraction, the acetabulum and head and neck of the femur are normal in a large percentage of cases.

2. With normal conditions prevailing, there is no reason why the condition should not be regarded and treated as a traumatic dislocation and replaced in the same manner, and the child permitted to go about.

When we compare the large percentage of good results accomplished by this method with those of the Lorenz method, and the great saving of time and mental suffering, this, in the future, must be the method of choice and trial, to be followed by the plaster-of-Paris fixation, if there develops a failure of retention.

TREATMENT OF GOITER WITH INJECTIONS OF PHENOL, TINCTURE OF IODIN AND GLYCERIN

A FURTHER REPORT OF EIGHTY CASES*

JOSEPH EASTMAN SHEEHAN, M.D.

Instructor in Diseases of the Nose and Throat, New York Post-Graduate Medical School and Hospital; Consulting Otolaryngologist, St. Mary's Hospital and Port Jervis Hospital

AND

WILLIAM H. NEWCOMB, M.D.

Instructor in Diseases of the Nose and Throat, New York Post-Graduate Medical School and Hospital

NEW YORK

The injecting of diseased thyroid glands as a means of curing or relieving the pathologic condition has greatly interested us for the past five years. Through the courtesy of Prof. Beaman Douglass of the New York Post-Graduate Hospital, we have been able to observe all cases of goiter coming before us.

Eighty cases of all forms of goiter were injected at regular intervals by us for the past two years, with a mixture of equal parts of phenol (carbolic acid), tincture of iodine and glycerin. The eighty cases represented more than 500 injections. A limited number of the patients were injected with boiling water, but with poor results. We doubt its efficacy and we have discontinued its use.

There were no untoward results from injecting the goiters with the phenol preparations, disproving the statement of some that it is a blind, uncertain and dangerous procedure. It is true if one's technic is not perfect, there is a chance of entering a vein or of injecting too much of the phenol solution, thereby causing symptoms of acute strumitis. In four of the ten patients who were operated on there was some difficulty in separating adhesions between the anatomic and surgical capsule caused by the material oozing out, when the needle was retired from the gland.

The object of the injections is to produce an inflammation, which eventually causes a fibrosis in the gland and the obliteration of that part of the gland injected. After the case has favorably reacted to the treatment, one is able to feel islands of fibrosis. It gives one the feeling of a hobnail liver. The production of a fibrosis in the gland is borne out by the reports of the pathologists, when previously injected patients were operated on and were submitted for examination.

It will be seen from the accompanying table that the injections are particularly suitable in the ordinary parenchymatous goiters of young women. Of fifty-five patients of this type injected, 76.4 per cent. were cured. It relieves the thyrotoxicosis, as in exophthalmic goiter, but unfortunately the relief is only temporary. In fourteen toxic cases, relief was given in 80 per cent. It is of no avail in the cystic or colloid form; in fact, if

* In the Medical Record (92: 591 [Oct. 6] (1917) one of us (J. E. S.) published a report on seventeen cases of goiter, the treatment of which was similar to that described in this presentation.

the treatment is persisted in, it may do harm by causing a sudden enlargement of the gland which may seriously interfere with respiration.

The majority of the patients sought relief simply for the swelling in the throat. Some had slight difficulty in swallowing or lifting the arms upward. In other cases the swelling was brought to the attention of the patient by friends or members of the family. The majority of the patients noticed the swelling themselves.

RESULT OF TREATMENT IN EIGHTY CASES IN WHICH
PHENOL, IODIN AND GLYCERIN MIXTURE
WAS INJECTED *

Type of Goiter	No. of Patients	Cured	Improved	Unimproved
Parenchymatous	55†	42	10	3
Exophthalmic goiter	14‡	..	12	2
Cystic	8	8
Colloid	2	2
Adenomatous	1	1

* The number of injections ranged from three to twenty-six. All the patients were females except one, a male suffering from an advanced form of exophthalmic goiter.

† Fifty of whom were between 12 and 30 years of age.

‡ Eight mild cases, 6 advanced.

ACTION

The treatment causes an inflammation in the gland with a resultant fibrosis. It quiets the heart's action, improves the appetite, has a favorable effect on metabolism, stays emaciation, and reduces the mental irritability.

It is our custom to inject all goiters which are to be operated on, as the relief of the toxic symptoms is a powerful adjunct to the success of the surgical procedure. Patients are put to bed, but are allowed to get up daily for several hours to break the monotony, provided they do not display an excessive degree of thyrotoxicosis. A strict nonanimal protein diet is ordered, and small doses of codein at frequent intervals are given. The object is to produce mental and body quiet. Colonic irrigations of 2 per cent. sodium bicarbonate are given daily, as this is a powerful way of reducing the toxemia.

Two bowel movements should be obtained daily. The patient should have plenty of rest; noon and afternoon rest is insisted on. Plenty of alkaline water should be given. Patients with little means are advised to take plenty of water with the addition of a little sodium bicarbonate. Plenty of outdoor air and sunlight is essential. Tobacco and alcohol are prohibited. A cleansing bath should be given daily to promote perspiration.

Meat and fish are forbidden. Milk, buttermilk and food cooked with milk should be given. No soups are to be made from meat or fish stocks. Eggs, butter, bread, rice, cereals, cooked fruit and especially fruit juices prepared out of ripe fruit, should be given.

Of the fourteen patients with exophthalmic goiter, ten were operated on and all recovered, the results of which I attributed mostly to the preoperative treatment. Four cases of the series of fourteen proved inoperable, but the patients were greatly relieved by the injections and preoperative treatment. A careful history should be taken of all patients presenting themselves for treatment. An exhaustive examination of the throat should be made to determine the form of goiter present, as the injections are of no avail in the cystic or colloid forms.

METHOD

Five drops of equal parts of tincture of iodine, chemically pure phenol and glycerin are injected into the

most prominent part of the gland. The needle is plunged directly into the substance of the gland, and the patient is told to swallow. If the needle is in the gland, it will have a wide upward and downward movement during the act. If the needle is extraglandular, no such excursion of the needle will take place. Care should be taken to inject the material very slowly, as hasty injection causes great pain, which may be referred to the ears. Other times it will be referred to the jaw and sides of the neck. There is always some pain, which takes place after the fluid has been injected; but this subsides within a short time. If too much of the material is injected, alarming symptoms of acute strumitis may set in. Some patients feel weak; others may actually faint. The interval of treatment is generally five days, but the frequency of the injections will be in direct ratio to the reaction. Some may accept treatment every three or four days, others between the fifth and seventh day. It is never safe to inject more than 12 drops. After the fifth injection, one can readily determine the progress of the case. In some cases five injections suffice; in others, many more may be needed. In one case of the series of fifty-five, as many as twenty-six injections were given before a cure was effected.

CONCLUSIONS

1. A goodly percentage of parenchymatous goiters will be cured by this method.
2. It relieves the thyrotoxicosis in the graver forms.
3. It is of no use in the cystic and colloid forms, and never should be given.
4. It is a safe procedure if one's technic is not faulty.
5. It is given as a preliminary in all cases going to operation, with the exception of the cystic, colloid and cancerous forms.
6. It is the only hope of relief in the inoperable cases and those in which surgery is refused.

ADDISON'S DISEASE

MORRIS J. BALEN, M.D.

PHILADELPHIA

The case here reported presents the characteristic syndrome of Addison's disease, together with definite and conclusive necropsy findings confirming the diagnosis of this rare and unusual affection.

REPORT OF CASE

History.—E. L., a Norwegian tailor, aged 48, entered the Easton Hospital, 8:30 p. m., Oct. 28, 1919, complaining of "liver trouble," and extreme and progressive weakness. There was nothing noteworthy in his family history. He had had mumps and whooping cough in childhood; his past medical history was otherwise unimportant so far as known. He had been in fairly good health until about six months before, when he began to experience constant muscular fatigue, independent of exertion, and to be subject to spells of faintness, dull headaches and pain in his shoulders. These spells of faintness were often accompanied by shortness of breath, palpitation, chilliness, nervousness and dull cerebration. There was little or no cough or sputum. He had frequent attacks of indigestion, associated with epigastric pain and occasionally vomiting. His appetite of late had been poor, and his bowels more or less constipated. For the past six months, he had been growing progressively weaker, and on admission his weakness was extreme. Coincidentally with the beginning of his weakness, his skin became brownish. The pigmentation was gradual in appearance, and steadily progressed in intensity. He was told by friends that it was due to "liver trouble."

He smoked heavily and used alcohol quite freely. There was no history of venereal infection or of any accidents or operations.

Physical Examination.—The patient was apparently well nourished and well developed. The brownish pigmentation of the skin was more marked on the face, upper chest and hands, and there were many spots of deeper brown on the abdomen. There was slight, if any, pigmentation in the mouth. There was no dropsy or edema, and no glandular enlargements. The pupils were equal, and the reaction to light and distance was good. The conjunctivae were slightly icteric, and the finger nails somewhat cyanosed. The cardiac impulse was neither visible nor palpable. The heart was not enlarged, but its action was very feeble. The first sound at the apex was distant, of poor muscular quality, and was accompanied by a faint systolic murmur, which was not transmitted. Both lungs showed extensive infiltration, chronic in character, especially marked at the apexes. There were harsh exaggerated breath sounds, but no râles. The xiphoid cartilage was unusually prominent, and the costal arches wide and flaring. The abdomen was negative, except for the spots of deeper pigmentation just mentioned. There was a cystic tumefaction over the right instep, and there were some scattered yellowish spots on both feet. The swelling over the right instep was painless, and when it was punctured, clear serum escaped. The patellar reflexes were exaggerated. The blood pressure was very low: systolic 85 mm. of mercury, and diastolic 75 (?). The radial pulses were equal, small and of very low tension. The temperature was 98, the pulse 96, and the respiration 24. The urine showed a faint trace of albumin but no casts. No blood count was made. The patient was put on tincture of digitalis, 5 minims, every three hours, alternated with $\frac{1}{60}$ grain of strychnin sulphate subcutaneously. Twenty-four hours after admission the patient became pulseless, went into coma, and died suddenly at 10:30 p. m., October 29.

Necropsy Findings.—October 31, the lungs were found to be anthracotic. The right lung showed numerous miliary tubercles scattered throughout all the lobes, with several small areas of calcification in the upper lobe and a calcareous plaque, about 12 mm. in diameter, at the extreme apex. The pleura on the right side was greatly thickened, and there were adhesions between the costal and visceral layers. Numerous miliary tubercles covered the diaphragmatic surface of the pleura on the right side, and tubercles were also found on the under surface of the sternum. The left lung presented a crater-like ulceration at the apex, about 3 cm. in diameter, with an irregular surface and ragged margins. Section revealed many miliary tubercles, with here and there a calcareous nodule—evidence of healed lesions. The lower lobe and pleura were comparatively free from tubercles. The heart was negative except for some roughening of the mitral leaflets. The abdominal viscera were surrounded by considerable fat. The spleen was about twice its normal size, and on section appeared quite friable, but free from tuberculous deposits. The other abdominal organs, except the suprarenals, showed nothing abnormal.

Suprarenals.—The left suprarenal was many times its normal size, and about three times as large as its fellow on the opposite side. On section, both presented an appearance not unlike that of brain tissue. There was great atrophy of the cortex, and extensive and diffuse fibrocaseous degeneration of the medullary portion, with only minute islands of the original gland tissue remaining. Microscopically, the capsule was seen to be thickened. The histologic distinction of the various zones of the cortical portion could not be made out. A number of small, but typical, tubercles occupied that portion of the cortex corresponding to the zona glomerulosa of the normal suprarenal gland. The medullary portion was the seat of a uniform and diffuse caseation.

COMMENT

This history of a condition with an obscure and insidious onset, with profound and progressive asthenia, general debility, feeble heart action and circulation, low blood pressure, nervous and mental depression,

digestive disturbances and a brownish pigmentation of the skin, immediately brings to one's mind the characteristic syndrome of Addison's disease. The finding at necropsy of tuberculosis of the lungs and of the suprarenals, together with enlargement of the spleen, completes the clinical picture of this rare disease. The very low blood pressure was probably due to an alteration, insufficiency or total suppression of the internal secretion of the suprarenal bodies in consequence of their destruction by tuberculosis. The sudden death precluded any attempts at suprarenal treatment. It is doubtful, however, if such therapy could materially influence the course of the disease in a person whose system had been irreparably damaged by grave and extensive lesions of tuberculosis. The strange feature in this case is the absence of a history and symptoms of pulmonary tuberculosis.

CONTROL OF DIPHTHERIA BY CULTURES OF THE NOSES AND THROATS OF SCHOOL-CHILDREN

L. B. GLOYNE, B.S., M.D.

Health Commissioner

KANSAS CITY, KAN.

The importance of taking swabs from the throats of schoolchildren for the controlling of diphtheria has not been fully recognized by a number of public health officers. In one section of Kansas City, Kan., called Argentine, we have a district that is isolated by natural boundaries. The Kansas River bounds this district on the north and east, while large hills form a natural boundary on the west and south. The retail trade, the milk supply and the school system are all confined within these limits.

Oct. 1, 1919, we had fourteen cases of diphtheria in this district and none in the rest of the city. We took cultures of the schoolchildren, 367 in all, and found thirty-four carriers. One of these was a child who had had diphtheria one month previously and had been released from quarantine after having had only one negative culture. This child had been given antitoxin at the time he was suffering clinically from diphtheria. The physician in charge thought that because antitoxin had been given, the diphtheria bacilli were killed, and the child was safe to return to school.

We placed these carriers in quarantine and required two negative cultures, taken in the homes, from each of these before they could return to school. Only two new cases developed in this community. One was in a child who had had a positive culture, and the other was in the home of a carrier. In the rest of Kansas City, Kan., scattered in all districts, thirty-three new cases soon developed.

The only one of these carriers who was given the antitoxin was the child who developed diphtheria clinically. All the rest cleared up entirely within three weeks, only throat swabbing, gargles and nose syringing being employed. We all doubt the efficacy of this treatment, but we cannot completely disregard our findings in these cases.

CONCLUSIONS

1. The swabbing of the throats of the children should be a measure adopted at the outbreak of a single case of diphtheria in a school.

2. The quarantine of carriers is as essential as is the quarantine of those suffering from diphtheria, in the controlling of an epidemic of diphtheria.

3. Two negative cultures should be required as the minimum from all children who have had a positive culture. A negative culture means something, but does not have the significance that a positive culture has.

4. Antitoxin has a very definite place in giving immunity against diphtheria, but it does not kill the diphtheria bacillus; so those who have had diphtheria may continue to be carriers for an indefinite time, if great care is not taken in getting at least two negative cultures from them.

5. Carriers usually clear up entirely without the use of antitoxin.

A CASE OF CEREBROSPINAL MENINGITIS DUE TO A DIPHTHEROID BACILLUS*

GEORGE F. DICK, M.D.
CHICAGO

While the part played by pseudodiphtheria bacilli in pathologic processes has been much discussed, they have not been recognized as the cause of meningitis, and those found in the nose are usually considered unimportant. Cases such as the one reported here are doubtless rare; but they are important in their bearing on the pathogenic possibilities of pseudodiphtheria bacilli.

REPORT OF CASE

A white man, aged 49, admitted to the service of Dr. James B. Herrick, June 20, 1919, with a family and personal history which gave no information bearing on this illness, two weeks before admission had fallen in the bathroom as the result of a shock received from a defective electric fixture. Three days after the fall he began to complain of headache and "seemed feverish." After ten days of persistent headache, he was brought to the hospital.

He was a well developed, well nourished man. The mouth temperature was 104.8 F., the pulse 88, the pharynx was red, the tonsils were small, the teeth were in bad condition and the cervical glands were palpable. There were dulness and subcrepitant râles over the left lower chest anteriorly, and in the axilla. The patient was drowsy, the knee and ankle reflexes were active, and flexion of the neck increased the headache. Roentgenograms of the head revealed no fracture. The erythrocyte count was 3,980,000; the leukocyte, 12,600, and hemoglobin, 65 per cent. The urine contained a trace of serum albumin and some leukocytes, but no casts.

The patient's condition grew progressively worse, and he died five days after admission, on the fifteenth day of the disease.

Spinal puncture on admission yielded a cloudy fluid containing 746 leukocytes per cubic millimeter, 54 per cent. of which were polymorphonuclear neutrophils, and the rest lymphocytes. The sediment was blood tinged. The ammonium sulphate test for globulin was positive, and the colloidal gold test indicated meningitis (0011234432). Wassermann tests of the cerebrospinal fluid in 0.2, 0.5 and 1 c.c. amounts were clearly negative. No tubercle bacilli were found in direct smears of the sediment. A guinea-pig inoculated subcutaneously and intraperitoneally with the sediment, and killed at the end of six weeks, showed no tuberculous lesions. Organisms were found in Gram's stains of direct smears of the cerebrospinal fluid. They were gram-positive, short, diphtheroid bacilli which most frequently occurred in pairs, end

to end. They were often within the leukocytes. In methylene blue stains they did not show polar bodies, and were shorter than the usual forms of diphtheria bacilli.

Aerobic and anaerobic goat blood agar slants and agar shake cultures were made of the fluid. At the end of twenty-four hours' incubation, all tubes contained in pure culture the gram-positive bacillus found in direct smears. In the shake culture made with 1 c.c. of the cerebrospinal fluid, the colonies were so numerous that it was impossible to count them. The bacillus grew both aerobically and anaerobically on the surface of goat blood agar, producing a delicate grayish film, or isolated, slightly convex, grayish colonies less than a millimeter in diameter. The blood was not changed. The growth on goat blood agar was more luxuriant than on plain agar or Loeffler's serum. The bacillus grew but produced no acid or gas in maltose, raffinose, saccharose, lactose, salicin, mannite, dulcitol, inulin, galactose, or dextrin azolitmin broth. In glucose azolitmin broth, it produced acid without gas. It had no effect on milk. Broth cultures were clear, with a finely granular sediment. In twenty-four hour old cultures the bacillus was not motile.

A guinea-pig inoculated intravenously with two twenty-four hour slants of the original culture died twenty-two hours later. There was a marked fatty degeneration of the liver, and a blood-tinged cerebrospinal fluid, which contained the bacillus in pure culture. Two guinea-pigs were inoculated intraperitoneally with a forty-eight hour broth culture of the organism, and one of them also received diphtheria antitoxin; neither of these pigs died.

Cerebrospinal fluid obtained from the patient three days later showed a negative Wassermann test in 0.2, 0.5 and 1 c.c. amounts. There were no tubercle bacilli in the smears. Cultures contained numerous colonies of the bacillus described. No other organisms were found in any of the cultures.

A blood culture the day following the first lumbar puncture showed about one colony of a gram-positive bacillus from each cubic centimeter of blood. Morphologically and culturally, it was identical with the organism found in the cerebrospinal fluid. A Wassermann test of the blood was negative.

COMMENT

The organism described differs from the diphtheria bacillus in the absence of polar bodies; failure to acidify maltose and dextrin; and in being not pathogenic for guinea-pigs on intraperitoneal injection of a forty-eight hour broth culture.

Eberson¹ has made an attempt to group diphtheroid organisms. He finds that strains isolated from the eye and nose are usually in the nonfermenting or in the glucose splitting group. The bacillus found in this case of meningitis resembles in morphology and staining properties Hofmann's type of pseudodiphtheria bacillus. It constantly fermented glucose with the production of acid. The pathogenicity of the bacillus for guinea-pigs was discovered only by intravenous inoculation: according to the method usually employed for testing the virulence of diphtheroids, it would be classed as nonvirulent.

On the whole, it is probably best considered as a pseudodiphtheria bacillus closely related to that described by Hofmann. It may be pathogenic for man, as in this case it was doubtless the cause of the fatal meningitis; and is pathogenic for guinea-pigs on intravenous, but not on subcutaneous or intraperitoneal inoculation.

637 South Wood Street.

A PLASTIC OPERATION FOR THE CURE
OF URETHRAL STRICTURE

MAXIMILIAN STERN, M.D.

NEW YORK

In view of the fact that external urethrotomy can never promise a lasting benefit and is never performed with the hope of effecting a cure, it is my opinion that it should be replaced by an operation that is logical to that end.

Russell's partial resection, Marion's radical resection and Cabot's plastic operation are operations which have advantages over external urethrotomy, but which are more or less difficult of performance, because of injury to the corpus spongiosum which causes hemorrhage and obscures the field.

In a previous communication¹ I reported four cases of urethral stricture, with acute retention of urine, treated without external urethrotomy, and I made reference to an operative procedure, which I thought, at that time, promised lasting results.

In that communication there was a report of one case of urethral stricture in a patient on whom previous external urethrotomy had been performed and who had a frankly cicatricial stricture at the bulb. With the operation that I am about to describe, this patient was apparently cured, as a recent examination has proved.

PURPOSE OF THE OPERATION

By the method that I am about to describe it is purposed to excise the strictured floor at the bulbomembranous junction without inflicting injury to the overlying structures or to any other portion of the urethra.

Figure 1 indicates the location of strictures most commonly encountered in their relation to the anatomic structures overlying and to the triangular ligament.

The muscle structures are separated, thus exposing the corpus spongiosum, as subsequent illustrations will show. The corpus spongiosum is detached from the triangular ligament and elevated from the urethra, thus exposing the strictured area. This is excised and a repair is made in a horizontal direction, thus preventing any diminution in the lumen of the urethra. The structures overlying are then restored to their normal positions, as indicated in Figure 2. With the indwelling catheter in the urethra for several days and the several layers of tissue securely sutured over the urethral wound, primary union is logical and no escape of urine through the perineal wound should occur.

PREOPERATIVE PREPARATION OF
THE PATIENT

In patients presenting themselves with acute retention of urine and in an anxious and desperate state incident to many sleepless nights and vain endeavor to micturate, it seems inadvisable to introduce the additional risk of an ether narcosis. In such extreme

Fig. 1.—Diagrammatic representation of stricture at bulbomembranous junction; staff in urethra arrested at stricture; filiform through stricture into bladder. The corpus spongiosum overlying the stricture and attached to superficial layer of the triangular ligament will be noted.

Fig. 2.—Diagrammatic representation of finished operation: A, stricture excised and sutures in place; B, corpus spongiosum replaced over urethra and sutured.

Fig. 3.—A, bulging caused by staff in urethra, the lower arrow corresponding to beak of staff at stricture; B, inverted V incision, its apex well above stricture.

Fig. 4.—Skin flap turned down, exposing structures overlying corpus spongiosum: A, ischio cavernosus muscle; B, bulbocavernosus muscle; C, junction of the superficial transverse perineal and bulbocavernosus muscles on corpus spongiosum; D, levator ani muscle.

Since that time an operation has been performed in like manner in six other cases that were not amenable to palliative measures, with results that have seemed perfect.

cases the preliminary introduction of a ureteral catheter through the stricture with the aid of the author's instrument, as described in another communication,² will be found a valuable preoperative measure.

1. Stern, Maximilian: Four Cases of Urethral Stricture with Acute Retention of Urine Treated Successfully without External Urethrotomy, *Internat. J. Surg.* 32: 180 (June) 1919.

2. Stern, Maximilian: The Easy Penetration of Urethral Strictures: Operating Urethroscope of the Gerringer Type, *J. A. M. A.* 73: 1360 (Nov. 1) 1919.

The rehabilitation of the patient and the amelioration of cystitis and urethral edema will do much toward making a radical operation successful. These can be accomplished only by giving the patient several days of respite from his vesical urgency. Through a ureteral catheter the urine dribbles away into a receptacle, and uninterrupted sleep can be obtained.

At the apex of the denuded area, the bulbocavernosus muscles are separated from above downward in a median line, the corpus spongiosum being avoided, while care must be taken not to puncture the structure (Fig. 5).

These muscles cleave easily from the corpus spongiosum, as far downward as the superficial transversus

Fig. 5.—A, bulbocavernosus muscles separated and held apart, permitting corpus spongiosum (B) to protrude.

Fig. 6.—B, clamps grasping junction of bulbocavernosus and superficial transverse perineal muscles near their attachment to corpus spongiosum; A, right side severed, exposing C, superficial layer of the triangular ligament; D, muscle stump remaining attached to corpus spongiosum.

Fig. 7.—A, corpus spongiosum elevated, exposing urethra; B, beak of staff engaged in stricture in urethra throwing it into folds, C; D, same, lateral view; E, Allis clamps placed above and below stricture and line of incision.

The back pressure on the kidneys is relieved and the general condition of the patient is improved.

THE OPERATION

The patient is placed in an exaggerated lithotomy position, with a sandbag under the buttocks, in order to bring the perineum into a higher plane than a vertical one—almost approaching the horizontal. An inverted V incision is made, the apex of which corre-

sponds to a point about 1 inch above the position of the beak of the staff in the urethra, its lower arms extending nearly to the tuber ischii (Fig. 3). The skin flap is dissected carefully, so as not to injure the thin muscle layers overlying the corpus spongiosum (Fig. 4).

perineal muscles. At this point they are firmly fixed with the superficial transversus perineal muscles to the corpus spongiosum. A hemostat is placed so as to grasp the insertion of these two muscles on either side and an incision is made mesial to the

Fig. 8.—Urethra opened; staff and filiform exposed; left stricture bearing flap being removed.

Fig. 9.—Same as Fig. 8; aperture in urethra after removal of stricture tissue may be seen.

Fig. 10.—Soft rubber catheter inserted into bladder; open end of catheter slipped over beak of staff about to be drawn up through urethra.

sponds to a point about 1 inch above the position of the beak of the staff in the urethra, its lower arms extending nearly to the tuber ischii (Fig. 3). The skin flap is dissected carefully, so as not to injure the thin muscle layers overlying the corpus spongiosum (Fig. 4).

hemostats, so as to leave a muscle stump attached to the corpus spongiosum (Fig. 6). Two lateral spaces now appear beside the "butt-end" of the corpus spongiosum, into which the finger easily penetrates to the superficial layer of the triangular ligament, and it will be observed that the cor-

pus spongiosum is fixed to this structure. With the aid of scissors the elevation of the corpus spongiosum from the triangular ligament and from the urethra itself is easy of accomplishment. This procedure is carried as far as may be necessary, that portion of the urethra in which the staff is arrested and a short distance above it, being thus exposed. The

Fig. 11.—A, catheter in urethra; first suture placed for approximation of upper and lower angle of wound; B, suture tied.

strictured urethra is now exposed to view, and when the tip of the staff is pressed downward the urethra below the point of engagement will pucker in advance of it (Fig. 7).

Two Allis clamps grasp the urethra, one above the strictured area and the other well below it. A linear incision in the midline is made between these two points, by which the strictured area is opened. Allis clamps are attached to the free edges, the interior of the urethra being thus exposed, while the beak of the staff and the filiform are brought into view (Fig. 8). These two lateral flaps are removed with scissors, an ovoid fenestra being left in the urethra (Fig. 9). A rubber catheter, size 22 F., is now inserted into the bladder and the filiform removed. The open end of the catheter is slipped over the beak of the staff, and withdrawn through the urethra (Fig. 10). Urethral repair must now be made. It will be found that there is ample urethral tissue for the transverse repair without causing even slight tension (Figs. 11 and 12).

REPLACEMENT IN THEIR NORMAL POSITIONS OF ALL THE STRUCTURES OVERLYING THE URETHRAL WOUND

1. The corpus spongiosum is attached to the superficial layer of the triangular ligament by two sutures of fine catgut.

2. A single suture is placed in such a manner (Fig. 13) as to bring the two bulbocavernosus muscles and the transversus perinei muscles in apposition with the muscle stump remaining on the corpus spongiosum. This suture also includes the levator ani, which frequently drops away when the transversus perinei muscles are severed.

When this suture is tied, the structures are restored to their original positions and the union of the bulbocavernosus muscles completes the muscular repair (Fig. 14).

The skin flap is now replaced with interrupted silk or linen sutures. It will be observed that there are three distinct coverings over the urethral wound. The close apposition of these structures may be confidently expected after from forty-eight to seventy-two hours, during which time the catheter remains in the urethra. After the expiration of this time, no urinary leakage is to be expected, and the patient is permitted to void.

POSTOPERATIVE TREATMENT

The indwelling catheter is fixed to the glans so that the eye of the instrument is situated just inside the internal vesical sphincter and fastened with an elastic device

manufactured for that purpose, or by any of the methods improvised by urologists. It is allowed to remain in situ for forty-eight hours, the patient being cautioned during this time not to make any urinary effort. At the expiration of forty-eight hours the catheter is slowly withdrawn, while a gentle stream of hot boric acid solution is flowed through it. A sterile catheter is then inserted and allowed to remain twenty-four hours. This concludes the third postoperative day. On the fourth postoperative day the patient is catheterized every four hours or when request is made. On the fifth day, voluntary micturition is permitted.

Fig. 13.—A, corpus spongiosum replaced over urethral wound and sutured to superficial layer of triangular ligament B, single suture so placed as to restore all muscle structures to their original positions over "butt-end" of corpus spongiosum.

Fig. 14.—A, suture tied; B, union of bulbocavernosus muscles.

The care of the perineal wound includes certain important considerations in order to accomplish primary union. In a moist, bacteria-laden area, frequent changes of dressings must be made and perspiration prevented, if possible by avoiding heavy bedclothes.

Immediately after the operation, it is my practice to cover the operative field with an unguent, comprising paraffin, wax and petrolatum, which acts not only as an occlusive covering, but also as an antiseptic, in that it envelops any organisms present in the skin and renders them inert.

A sound (24 F.) is passed on the tenth day, and one of larger size a week later. It is my experience that no further instrumentation is necessary.

CONCLUSIONS

1. Since all, or nearly all, strictures occur anterior to the superficial layer of the triangular ligament, this operation can easily reach them. Extravasation of urine or infiltrating abscesses are not to be feared in a surgical procedure that does not disturb the membranous or prostatic urethra lying posterior to the triangular ligament.

2. An operation which is directed precisely to the diseased area, and which does not inflict injury to any other part of the urethra, must be conceived as a logical step toward a cure, and as superior to procedures heretofore in vogue.

219 West Eighty-First Street.

CARCINOMA OF THE EXTERNAL EAR

RICHARD L. SUTTON, M.D.

KANSAS CITY, MO.

To the uninitiated, the successful treatment of early, superficial carcinoma of the external ear may seem a comparatively simple matter; but after one has acquired a little experience in combating even the

cancerous involvement, the chronic inflammatory changes to which it is subjected, together with the poor blood supply, prevent prompt healing, even after the removal of the parent cause of the trouble.

Fig. 2.—Very early basal-cell carcinoma of ear, showing effects of radium treatment: *A*, cellular infiltration; *B*, changes in connective tissue; elastic fibers broken and twisted; *C*, cartilage; hematoxylin-eosin stain; low magnification.

During the past two years, I have had opportunity to study seventeen cases of carcinoma of the ear. All the patients were men. The youngest was 28, the oldest 81 years of age. In five cases studied microscopically, all the growths were of the basal-cell type.

Owing to the character of the structures involved, the histologic picture differs in some minor respects from that seen in basal-cell carcinoma of other parts of the body.

In thirteen instances, the growths had developed from seborrheic keratoses, usually of the keratotic variety, and in nearly every case there was a history of primary injury, such as a cut or a bruise. Eleven of the patients, at one time or another, had suffered from frost-bite.

All the lesions developed at some point above the level of the floor of the external auditory meatus. In no instance was the lobe primarily involved. The upper portion of the helix was a favorite site for the development of the lesions, probably because of its exposed position. Occasionally the cranial surface of the pinna was attacked, in one instance following an injury from a spectacle bow, and in another a slight cut from a razor, inflicted by a barber while trimming the hair.

There was a striking similarity in the case histories. Following a slight injury of the ear, generally at some point on the helix, the patient developed a small, superficial ulcer, which healed very slowly. The retarded healing was, in a measure, the fault of the patient himself. If the scab was not deliberately scratched off, because of the slight irritation to which its presence gave rise, it was accidentally rubbed off by the too vigorous use of a rough towel. Finally, the lesion apparently healed, but a small keratosis developed at the site of the former wound.

Fig. 1.—Basal-cell carcinoma of helix: *A*, epidermis; *B*, connective tissue of dermis; *C*, masses of cancer cells; hematoxylin-eosin stain; low magnification.

milder type of the disorder in this region, a pessimistic attitude generally replaces the former optimistic one.

The difficulty of bringing about a cure in these cases is largely due to the fact that the skin lies very close to the cartilage; and even if the latter escapes direct

The growth of the little hyperkeratotic tumors may have been retarded by the frequent application of grease or petrolatum; but in the course of months or years, a large percentage of them became malignant. The subjective symptoms were at first comparatively slight, and consisted of itching and burning of variable degree, easily allayed by a mild antipruritic. Later, as the carcinoma developed, and the deeper structures were invaded, the patients frequently complained of a throbbing, penetrating pain, which often involved the entire side of the head, and which only narcotics would relieve.

The plan of treatment varies with the character, stage and extent of the lesion. In growths of the prickle-cell type, early and radical excision is the best and safest course. The basal-cell tumors are less serious, and more weight can be given to the importance of a good cosmetic result when it comes to dealing with them.

Fig. 3.—Early basal-cell carcinoma of ear: *A*, strand of cancerous tissue extending downward from basal layer of epidermis into corium; *B*, thickened prickle layer; *C*, derma, with masses of new growth lying between the bundles of connective tissue; hematoxylin-eosin stain; low magnification.

As a prophylactic measure, the ears should be suitably protected from cold during the severe winter months. Frost-bite may not be a direct causative factor, but repeated injury from this source undoubtedly predisposes to cancer.

Even slight lacerated wounds of the ear should receive proper surgical attention. In treating rough, jagged injuries of the skin, the edges should be pared down and carefully approximated, and the wound properly closed and dressed.

Seborrheic keratosis, which are often the precursors of the more serious lesions, can sometimes be successfully combated by the daily use of a mild keratolytic, such as salicylic acid ointment (10 per cent.). Also carbon dioxid snow is a valuable remedy in some instances, although its field is limited, and in suspicious or advanced lesions, more harm than good is liable to follow its use. This is due largely to the fact that its destructive action is not that of a direct escharotic, but a sequel to the acute inflammatory changes that follow intense refrigeration.

The widely dilated vessels, together with the lowered vitality of the immediately adjacent tissues, tend to extension rather than eradication of the lesions attacked. The actual cautery is a much better agent

Fig. 4.—Late basal-cell carcinoma of ear: *A*, connective tissue of derma: only a bridgework remains; *B*, masses and strands of cancer cells penetrating the fibrous network; hematoxylin-eosin stain; low magnification.

in these intermediary or frankly malignant cases. The destruction of the lesion is certain, for, as Hazen, Bloodgood, MacKee and others have shown, the efferent vessels are promptly sealed off, and the liability to

Fig. 5.—Late basal-cell carcinoma of ear, showing involvement of cartilage at *C*: *A*, disorganized strands of connective tissue; *B*, irregular masses of cancer cells; hematoxylin-eosin stain; moderate magnification.

peripheral extension is reduced to a minimum. Unfortunately, the tissues in this vicinity do not heal very promptly following actual cauterization, and the ensuing burns are frequently a source of extreme discomfort to the patient. Fulguration is painful and, as

ordinarily practiced, unreliable. Of the various chemical caustics, arsenous oxid, as recommended by Robinson, is probably the best; but when employed in this locality, it is open to the same objection as the actual cautery.

Prior to the involvement of the cartilage, many of the cases respond very satisfactorily to roentgen-ray

In the treatment of basal-cell carcinoma of the ear by means of radium, a severe reaction is seldom necessary, and in the superficial cases should always be avoided. The skin in this region is very thin, and affords only slight protection to the underlying structures. The inflammatory changes that occur as a result of prolonged exposures subside very slowly, and weeks

Fig. 6.—Basal-cell carcinoma of ear involving cartilage of eighteen months' duration; very painful.

Fig. 7.—Multiple basal-cell carcinoma of the ear; of three years' duration; no lymph node involvement; radical operation, followed by cure.

Fig. 8.—Carcinoma of the ear, showing ulcer that remained after radium therapy. Lesion healed under the action of soothing local applications in seven weeks; no recurrence had taken place one year later.

treatment and especially to radium. If the former agent is employed, only the intensive method should be used, otherwise the result is liable to be disastrous rather than beneficial. I once saw a case of superficial carcinoma of the concha which at the time could readily have been successfully removed by a competent surgeon in

or even months may elapse before the ulcer marking the site of the former carcinoma is entirely healed. The healing process can sometimes be expedited by the cautious use of liquor hydrargyri nitratis, a remedy first suggested to me by my friend, Dr. T. S. Blakesley. The agent is applied by means of a tooth-pick, and its action is promptly halted at the end of one or two minutes by a liberal coating of sodium bicarbonate. Occasionally, diluted citrine ointment (unguentum hydrargyri nitratis, 1 part; petrolatum, 7 parts) will prove helpful at this stage of the disorder. Cleanliness is essential, for, as Dr. Du Noüy has said, the ideal conditions of perfect and rapid healing are realized when a wound is kept practically sterile, or deprived of pathogenic micro-organisms, as cocci, diplococci and streptococci.¹

In those cases presenting cartilaginous involvement, I have found both radium and roentgen-ray treatment useless. Prompt excision is the best and safest plan, and in the hands of a skilled operator, the results are generally good. As a rule, the ensuing deformity is comparatively slight, and the patient is promptly relieved of a disorder that is liable ultimately to prove both distressing and dangerous to life.

Fig. 9.—Basal-cell carcinoma of the ear in a man of 70; the growth was destroyed by means of radium, but the lesion healed very slowly, and was extremely painful.

Fig. 10.—Seborrheic keratosis on helix which developed following slight cut from razor and ultimately became malignant.

about fifteen minutes. Nine months later, I again saw the case, but during the interval the patient had received more than a hundred brief roentgen-ray exposures in and around the affected area. The combination proved too much for him, however, and the man died.

Altruism.—Sympathy for manifest evils, and self-sacrifice for others have no limit when the emotions are directly stimulated.—Brend.

TUMORS OF THE BLADDER

THEIR DIAGNOSIS AND TREATMENT

ROBERT H. HERBST, M.D.

AND

ALVIN THOMPSON, M.D.

CHICAGO

Tumors of the bladder comprise but a small percentage of all the tumors of the body, this being variously estimated at from 0.75 per cent. to as high as 5 per cent. of the total number. Of these, approximately one half are malignant, and most of the remainder potentially so, in that they later become malignant.

TYPES OF BLADDER TUMORS

There are two common varieties of bladder tumors: papilloma and carcinoma. The papillomas are fibrous, benign or malignant, and the carcinomas adenoid or diffuse, adenomas being very rare.

Besides these common varieties of epithelial origin, other types of tumor are found occasionally, including myomas, angiomas, fibromas and various types of sarcomas. The papillomatous growths, benign or malignant, are by far the commonest form of tumor found in the bladder. Ewing¹ states that this is due to the structure of the mucous membrane and the physical conditions to which the tumors are exposed. The transitional type of epithelium accounts for the histologic varieties of tumors arising from it. The villous form is probably due to muscular activity and the constant bathing in fluid. Ewing further states that the long confinement of these tumors to the site of origin is probably due to their villous form rather than to a lack of lymphatics, which was once thought to be the reason.

Bladder papillomas occur in various forms, coarse or fine villous growths with more or less narrow pedicles, flat or lobulated forms, or they may be sessile. Papillomas vary greatly in size and are frequently multiple. The commonest location is in the trigonal area, especially about the ureteral orifices and the edges of the trigon. They have been observed at all periods of life, but are commonest after middle life, especially in the sixth decade. They occur about three times as frequently in men as in women. Their course is prolonged, and they have a tendency to remain confined to the bladder. A few of them remain benign for many years, but most of them become malignant eventually. Many are malignant from the beginning.

THE DIAGNOSIS OF MALIGNANCY

The question of malignancy is the all-important point in diagnosis. If a tumor is benign it can be removed by fulguration, and recurrences or additional tumors appearing later can usually be removed by the same means, whereas if it is malignant it is usually resistant to fulguration, and other or additional means must be

used. The macroscopic appearance of a tumor is not a certain guide in judging its malignancy. However, there are certain characteristics which may be taken as evidence of malignancy in papillary tumors, as necrosis or sloughing, calcific incrustations, edema about the base of the growth, nodules in the mucosa near the growth, the presence of an intractable cystitis, an induration felt through the vagina or rectum, and multiplicity or great size and the slow response to fulguration. The sessile growths and the flat warty or the extensive velvety patches on the wall of the bladder are quite sure to be malignant. If a piece is removed through the cystoscope for examination, it may have benign characteristics even though the pedicle or base may be actually malignant. However, the

Fig. 1.—Excision of papilloma of bladder with electrocautery knife: *a*, method of grasping pedicle of tumor with forceps and excising it with electrocautery knife; *b*, electrocautery knife; *c*, method of applying radium to former site of tumor.

removed portion may show actual malignancy. Then, of course, the diagnosis is assured. The removed portion may not show well-defined malignant characteristics and still give evidence of malignancy by exhibiting unusual growth capacity. Buerger² gives, in addition to the usual well-defined microscopic evidences of malignancy, these morphologic criteria on which the diagnosis of carcinoma or carcinomatous change in papillomas may be made: "Cells manifesting irregularity in size and shape; nuclei rich in chromatin, deeply staining and of bizarre shape; cells with atypical mitosis; giant cells and multinucleated cells."

Extension of malignant tumors may occur through the bladder wall to other pelvic structures, up the

1. Ewing, James: *Neoplastic Diseases*, Philadelphia, W. B. Saunders Company, 1919.

2. Buerger, Leo: *Tr. Am. Urol. A.* 9: 14, 1915.

ureter to the kidneys, and along the pelvic lymphatics to the prevertebral lymph nodes. Cases of metastases from bladder tumors have occurred in remote organs; but such metastases are comparatively rare and occur late.

Bladder tumors may be complicated by secondary anemia from hemorrhage, by cystitis, by hydronephrosis complicating tumors which may occur about or within the ureteral orifices, and by renal suppuration. Serious kidney complications may occur in those cases, benign or malignant, wherein blood clots or fragments or parts of the tumor interfere with the emptying of the bladder resulting in back-pressure from retention.

There is one dominating symptom which should be investigated by cystoscopic examination of the bladder without delay, and that symptom is hematuria, especially of the painless intermittent type. Neglect in giving prompt heed to this early warning has allowed too many papillomas to develop undisturbed until the bleeding has become profuse or the later attending symptoms, pain and frequency, have made investigation urgent. By that time the growth may have reached a large size or have become malignant, if not originally so, making the treatment not only more difficult, but too often less effective.

ETIOLOGY

The etiology of bladder tumors, like that of neoplasms in other parts of the body, is not definitely established; but many observers have noted that in a large number of cases there is a definite history of an irritation of some kind, as cystitis or stone. Bladder tumors appear to be common in anilin workers. These observations seem to indicate that irritation may predispose toward the formation of the growth.

Besides these primary growths of the bladder, secondary growths are not uncommon, spreading from the kidney, abdominal or pelvic viscera, and especially from the prostate.

TREATMENT

The treatment of bladder tumors has been more or less discouraging in the past, especially before the day when cystoscopy made early diagnosis possible. The choice of method to be used should be based on the pathology of the tumor. This, as we

have stated, cannot always be determined accurately. If the tumor is thought to be benign, there is no question but that the fulguration method described by Beer in 1910 gives the best results with the least discomfort to the patient and the lowest rate of recurrences. This method is carried out by means of the high frequency current used through an operating cystoscope. The two types of current used in this procedure are the Oudin and the d'Arsonval. The Oudin, or monopolar spark, produces cauterization and coagulation through its marked local action at the point of application. The d'Arsonval, or bipolar spark, has a

deeper and less local action, producing coagulation by heat and a more extensive destruction. For this reason it must be used with more caution, especially when its action is directed to the base of the tumor close to the bladder mucosa, in order to avoid too deep destruction of the bladder wall. These fulguration treatments are repeated at intervals varying from five days to two weeks, depending on the local reaction following each treatment and the progress made. Almost all benign papillary growths are readily removed by this method, and even some of the malignant papillomas are wholly removed, though usually more slowly and with greater likelihood of recurrence.

Surgical removal of both benign and malignant bladder tumors is attended by a large number of recurrences. It seems that fragments of the tumor even of the benign type are readily transplanted, producing recurrences either at the original site or in other parts of the bladder. Gardner,³ in an analysis of 666 cases of bladder carcinoma, shows that in 224 cases of partial resection of the bladder there were recurrences in 43.7 per cent. of the cases;

while in 442 cases in which only the growth was excised, the percentage of recurrences was 88. Comparison of these two surgical methods shows that the more radical removal gives the better results. Total cystectomy in these cases is very discouraging, as there is not only a very high immediate mortality but the results otherwise are not favorable. Gardner³ reports ninety-six cases of benign papillomas removed by excision with recurrences in 35.5 per cent., while in sixty-

Fig. 2.—Carcinoma of the prostate: 1, radium needles inserted into prostatic tumor through cystotomy incision; 2, schematic sagittal section illustrating the direction in which the needles are pushed, and the depth to which they are carried.

3. Gardner, J. A.: Tr. Am. Urol. A. 9: 226, 1915.

one cases treated by fulguration only 13.1 per cent. recurred. This shows a decided advantage in favor of the fulguration method in benign papillomas.

Radium has now been used for a number of years in the treatment of malignant bladder tumors; and the results, while far from being satisfactory, have been somewhat encouraging. The unsatisfactory results are partly due to faulty application of the radium. As radium acts in proportion to the inverse squares of the distances from the tissue acted on, it is obvious that it must be placed directly on the tumor or inserted into the mass to get the maximum effect. It may be applied in a specially constructed sound or cystoscope and kept in place on the tumor by holding the instrument with special clamps designed to keep it from moving (Young).

AUTHORS' PROCEDURE

Our usual procedure with a tumor thought to be malignant, if located in an accessible part, is to excise the growth and with it resect the entire bladder wall of that region, using an electrocautery knife in preference to the ordinary scalpel. Those tumors located in parts of the bladder not easily accessible, such as the trigon about the internal urethral orifice or closely associated with the ureters, are excised through the open bladder, carrying the incision down to the muscularis (Fig. 1 *a*), using the electrocautery knife (Fig. 1 *b*), following which radium is applied (Fig. 1 *c*) to the denuded surface from which the tumor has been removed.

Sessile growths and those with broad pedicles may be treated by introducing needles containing radium directly into the growth. When this is not possible, the radium may be applied on a staff or sound either through a suprapubic opening or through the urethra, care being taken to keep it in contact with the involved area.

Many of the unsatisfactory results in the past may be charged to the inaccurate placing of radium in the bladder. It is of the utmost importance, therefore, that the radium be not only placed accurately but also kept in place throughout the entire exposure.

It is known that commonly prostatic cancer spreads to and involves the bladder wall; and for this reason, the treatment of certain types of prostatic cancer will be included in this paper. Radical excision of a malignant prostate cannot be carried out with any reasonable degree of safety and success, except in very early cases. Those cases of cancer of the prostate which are not too far advanced and which show no evidence of metastasis are thus treated with radium:

A suprapubic cystotomy is made with a liberal high opening so as to give easy access to the involved blad-

der neck. A bimanual examination is made to determine the limits of the tumor. By means of a needle carrier, a number of hollow needles, each containing a capsule of radium, are inserted directly into the mass about 1 cm. apart in different directions (Fig. 2). A silk guide attached to each needle extends out of the suprapubic wound, by means of which the needle is withdrawn (Fig. 3). These needles are left in place from twelve to twenty-four hours, depending on how much exposure is desired. It is surprising how little reaction occurs from these long exposures as compared to the extensive burns which we see on the mucous membrane of the bladder and rectum when the radium is placed directly on these membranes. One such exposure usually causes the removal of most of the upper part of the tumor, though it may be repeated in a few weeks if found necessary. As most of the tumors begin in the lower part of the gland, a second introduction of

needles is made into this part of the tumor by making a dissection through the perineum, exposing the prostatic mass, and introducing the needles carrying the radium into the mass from below.

We have not described this method of attacking the malignant prostate with the intention of reporting cures, because the time since operation has been too short (about two years); however, our results are sufficiently encouraging to warrant continuation of the method.

National Department of Health.—In the creation of a department of health, all of the bureaus or parts of bureaus and divisions and boards could be easily adjusted without the loss of prestige by any of them. Some functions could be consolidated into single bureaus. The plan should be constructive of the agencies we now have, certainly not destructive.

The Public Health Service, owing to its size and present organization, would constitute the main foundation on which to construct such a department. Its mobile corps of medical and sanitary personnel is an excellent one to expand so as to include in the commissioned corps all of the scientists and specialists transferred from the other departments in grades according to the nature of the work and experience of each. Furthermore, some provision should be made to commission high class specialists in the various branches of preventive medicine from civil life, in grades commensurate with their ability and experience. The mobile corps, as expanded, should continue under the supervision of the surgeon-general, and should perform all of the medical and sanitary duties for all of the bureaus and divisions of the department. The provisions for one well organized, disciplined mobile corps of highly trained health experts to perform all of the medical and sanitary duties for all of the bureaus and divisions will doubtless be an effective agency in coordinating the work of those bureaus.—B. S. Warren, *Pub. Health Rep.*, Dec. 5, 1919.

TWO CASES OF MONGOLIAN IDIOCY
IN THE SAME FAMILY*

IRVING H. PARDEE, M.D.

Assistant Chief of Clinic, Neurological Institute
NEW YORK

Recent endeavors to throw light on the etiology of Mongolian idiocy have resulted in considerable literature on the subject during the past few years. The rarity of its occurrence in more than one child in a family is an observation of universal note.

Goddard¹ has collected the histories of 322 cases of Mongolian idiocy, and in not one instance was there a history of more than one Mongolian child in the family. McClelland² remarks that it is a common observation that in no family was more than one Mongolian idiot encountered. Shuttleworth³ says that the production

Two Mongolian children of the same family and their next older brother, showing characteristic mongolian facies, spatula hand, and short thumb and little finger.

of more than one Mongol in the same family is a great rarity, he himself having heard of only two cases and having never seen any. He also reports the case of twins, one normal and the other a Mongol, as does Swanberg.⁴ Dr. Max Schlapp, in the course of examining mental defectives for the city of New York, has seen over 500 Mongols, and in a personal communication to me states that he has never seen two Mongolian children in a family. Van der Scheer⁵ has collected

reports of two families, one with two Mongols and the other with three, and states that he has been able to find on record the reports of several families in which more than one child presented the disease.

As this type amounts to about 5 per cent. of all types of imbecility, it assumes the proportion of a considerable problem, and a determination of its exact etiology will be a large factor in its prophylaxis.

The controversy over the relation of syphilis to Mongolian idiocy is not yet definitely settled; but to those whose experience has been large, the occurrence of a positive Wassermann reaction is only a coincidence. The proportion of positive Wassermann reactions obtained from groups of Mongols should be over 80 per cent., instead of under 15 per cent., if the causative factor were syphilis, and so far the brains of Mongols have failed to show the characteristic pathologic changes of the disease. Two families showing the apparently intimate relation between the two conditions are reported in the literature: In one, reported by Van der Bogert,⁶ first, a syphilitic child was born, second, a normal child, and third, twins, one of whom was a syphilitic of the Mongol type. Babonnieux and Villette⁷ tell of a family of four Mongolian children whom they consider congenital syphilitics because of two maternal miscarriages, the death of six other children when infants, the presence of hutchinsonian teeth in these offspring, and a buccal leukoplakia in the father.

The family that has come under my observation is interesting not only from a statistical point of view, owing to the fact that two of the children present classical textbook pictures of Mongolian idiocy, but also from an etiologic point of view, since it presents two possible etiologic factors.

REPORT OF CASE

Family History.—The father, an Italian by birth, aged 49, formerly a bookkeeper, now a postoffice clerk, came to this country before his children were born. His ancestors were of an intelligent class, including lawyers, physicians and druggists, and there is no history of mental disease. The mother, also of Italian birth, aged 42, was the daughter of an engineer. Her mother had diabetes. She is large, obese, and has always been well except for frequent frontal headaches. Her pregnancies have been borne without any difficulty, and she has eleven living children whose ages are 27, 22, 20, 18, 17, 15, 13, 11, 9, 7 and 4. Between the last two children, she had two induced miscarriages. All of the children above 15 have finished school and have then taken business courses so that they are contributing their bit to the support of this large family. Their mentality is unimpaired; several of them showing considerable promise. The two youngest children were never considered to be like the others; they were backward in their development and did not resemble the rest of the family, but the parents have noticed a decided similarity in appearance between these two.

History.—Robert P., aged 7 years, was born after normal but rather prolonged labor. He has always been well but slow to develop. He was brought to see me because of his failure to talk, his vocabulary being limited to single words. He is able to call his parents and some of his brothers by name, and he seems to understand a great part of what is said to him. He is easily embarrassed, good natured, and somewhat restless in his activity. Physically he is undersized and bears the following characteristics of the Mongol: He has blepharitis, almond-shaped eyes with oblique palpebral fissures, epicanthic folds and an external strabismus in the left eye; the mouth hangs open; the lips are thick and

the tongue is large and protruding, having deep transverse fissures and prominent papillae; the nostrils point forward from a broad, flat nose. The expression is dull and stupid. The skin is soft, dry, and slightly puffy with plenty of subcutaneous fat; the joints are lax, showing a hypotonus. The fingers are short and thick; the thumb is obliquely cut off and the little finger is only half the usual length. Besides these signs he has small genitals with undescended testicles, and until a few years ago he wet the bed. The teeth are very bad, and there is no sign of second dentition as yet.

Edward P., aged 4 years, was born after normal labor. His development was slow. This child wets himself, and is noisy, destructive, and ceaseless in his activity, but is affectionate and good natured. It was most difficult to persuade him to submit to examination and to be photographed. He cannot talk and makes only unintelligible noises. His physical status is the exact counterpart of that of his brother: bullet head, brachycephalic skull, grimacing face with slit eyes, blepharitis, drooling mouth, thick lips, protruding tongue, hypotonus, hand of the typical spatular type, and skin of the same quality as that of his brother. To describe one is to describe the other.

The illustration shows the characteristic facies and the spade hand of the younger, though the difficulty in controlling the children made a better picture impossible. As I could not obtain consent for a Wassermann test, those data are unavailable; but a survey of the family history, with nine healthy children previous to these two, and parents who have no evidence of the disease, seems to be sufficient to exclude syphilis.

COMMENT

In these two Mongolian imbeciles we have the last children of a large family, a potent argument for the theory that they develop from a parent in whom the germ plasma has become defective through exhaustion. A history obtainable in over 50 per cent. of Mongols is that the idiot child was the last one of a large family, when the mother was far advanced in her reproductive life, or else that the child was the product of a marriage union consummated late in life.³

Let us consider this hypophrenic type from the endocrine aspect, for it is almost impossible to observe this peculiar appearing creature without remarking the growth and the tissue abnormalities. For some time the few points of similarity between the Mongol and the myxedematous cretin have been emphasized and made the basis for thyroid medication; but how different is the restless activity of the former from the dull sluggishness of the latter. So far, absolutely no results have been obtained with thyroid feeding in mongolism. In this family there is a strong endocrine heredity especially on the maternal side; her mother had diabetes, and she herself is of a pronounced dyspituitary type with nasal eyebrows, spacing of the incisors, obesity, and frequent frontal headaches. The children with their dry, smooth, hairless skin, prognathous jaw, small stature, abnormal bony growth, and undescended testicles show some very definite signs which could be classed as polyglandular. Therapy along these lines has, thus far, failed to bring about any cures, but further work will, we believe, throw light on this probable etiologic factor.

74 West Forty-Eighth Street.

Aerial Dust.—Establishments devoted to the manufacture of abrasive materials may present conditions in regard to aerial dust content that can scarcely be equaled in any other industry. The study of such conditions and the devising of adequate means for so controlling them as to protect the workers in this trade from the menace of tuberculosis would seem to invite serious attention.—*Public Health Reports*, May 30, 1919.

A CASE OF LUMBOSACRAL PARALYSIS (TRAUMATIC)

G. B. HASSIN, M.D.

Attending Neurologist, Cook County Hospital

DAVID M. LEVY, M.D.

AND

W. E. TUPPER, M.D.

CHICAGO

The lumbosacral plexus comprises the ventral branches of a portion of the fourth and fifth lumbar nerves and of the three upper sacral nerves. The principal nerves arising from this plexus are the ante-

Fig. 1.—Drooping of left foot, and atrophy of entire limb.

rior crural (second, third and fourth lumbar nerves), external popliteal (fourth and fifth lumbar and first and second sacral), internal popliteal (fourth and fifth lumbar and first, second and third sacral) and obturator (third and fourth lumbar). A combined involvement of all these nerves occurred in the case here reported.

REPORT OF CASE

History.—A colored boy, aged 18, a laborer, admitted to the orthopedic service (Dr. Harger), Aug. 19, 1919, complaining of difficulty in walking, stated that about fourteen years before, while in perfect health, he fell on the floor with the legs widely stretched. For nine months he was unable to walk, having been all this time confined to bed. He asserted that up to four years before he had had little difficulty in walking, but

admitted that the left leg was always smaller and weaker than the right. Four years before, this leg became much weaker, and he would fall frequently because of sudden flexion of the knee joint. The whole left leg, he said, had a feeling of

being dead and colder than the opposite one, but there never was pain. The patient had had measles, smallpox, mumps, whooping cough, pneumonia (twice), influenza, gonorrhea (one and one-half years before) and multiple sores on the penis (a year before). The family history was good.

Examination.—The patient looked healthy, and had a marked left scoliosis in the lumbodorsal region; the left side of the pelvis was much lower and the left leg was atrophied, while the right thigh appeared hypertrophied. In standing, he kept the left knee slightly bent and the body bent toward the right (Figs. 1 and 2). In walking, he bent the body forward and to the left, and swung the pelvis, throwing the leg and foot which struck the ground. The muscles of the entire left lower extremity were greatly atrophied, flabby and weak. The leg was much shorter and thinner than the right. The right thigh in the middle measured 25½ inches, and the left, 19 inches; above the patella, 18 and 14¾ inches, respectively. The length of the left limb was 33¾ inches, that of the right,

Fig. 2.—Atrophy of left leg; tilting of pelvis; bent trunk; scoliosis.

36 inches. The thighs measured in length 18¾ inches on the right, 18½ on the left. The measurements of the calf muscles at three levels gave a difference of 3 inches in favor of the right side; above the ankle joint the difference was very slight (a fraction of an inch).

Passive movements of the joints of the affected side were exaggerated and somewhat limited in the ankle. Kernig's, Lasègue's and Patrick's "faber sign" were absent.

Active movements on the same side were all abolished except abduction and flexion of the leg. Thus the patient was totally unable to move, on the left side, the toes or the foot, and could not extend or cross the leg, and adduct or flex the thigh over the abdomen. In contrast to such an extensive motor lesion, the sensory disturbances repeatedly studied in various wards of the hospital were rather mild, in the form of patches of anesthesia and hypesthesia over the dorsal surface of the foot and anterolateral surfaces of the leg.

The affected muscles and nerves showed some electrical changes which were rather indefinite. The muscles supplied by the anterior crural and peroneal nerves, as well as these nerves themselves, gave a normal response to the galvanic current, while the posterior tibial and the obturator gave no response whatever. The faradic current was not available.

The roentgen examination detected no changes in the bones or joints (Fig. 3).

The reflexes, like the Achilles tendon and the knee, were lost on the left, the cremasterics were very inconstant; the plantar was absent, and the Babinski negative. Pupillary and genito-urinary changes were absent.

SUMMARY

The clinical findings can be summed up as a flaccid atrophic, partly degenerative paralysis of the left lower limb, with involvement of the main branches of the great sciatic nerve (external and internal popliteal nerves), anterior crural and obturator nerves. The paralysis was of fourteen years' standing, and occurred after a fall in a 4 year old child with the legs abducted. Recovery occurred nine months after the injury, was never complete, and for the last four years the condition had become worse. The extensive paralysis was associated with comparatively mild sensory and indefinite, rather unusual, electrical changes. Bone changes, in spite of a long duration of the paralysis, were totally lacking.

COMMENT AND CONCLUSIONS

The clinical findings in this patient very much resemble those observed by Lorenz,¹ Bernhardt,² Schuster,³ Bade,⁴ Peltesohn⁵ and others in patients after not altogether successful attempts at reduction of dislocated hip joints. Thus, Lorenz speaks of a "tearing paralysis" (*Zerrungslähmung*) of the sciatic nerve which he has observed twice in 360 cases of so-called

Fig. 3.—Tibia and fibula of affected side, lateral and front views; no changes.

bloodless reposition of the hip joint, while in five of his 360 cases there was a paralysis of the quadriceps from the same cause (tearing of the crural nerve), without sensory changes. Bade explicitly states that the forced abduction procedures are the factors which most frequently lead to paralysis (of the crural and sciatic nerves), which he found to occur in 2.1 per cent. of Lorenz's operations.

Fig. 4.—Long bones of the affected extremity in an old case of poliomyelitis.

Peltesohn comes to the same conclusion from his extensive clinical and experimental studies, though he admits also the possibility of the compression of the sciatic nerve between the trochanter and tuber ischii. In addition to the sciatic paralysis he and many other orthopedists observed also anterior crural paralysis ("from overstretching" the nerve) without any neuralgic pains or sensory changes. The combined lesion of the sciatic and crural nerves he explains, together with the rest of observers, as a "plexus lesion."

It is unquestionable that in our case, in view of the history of a trauma, long duration of the paralysis (nine months), and the presence of sensory disturbances, mild as they are, the lesion should be placed in the plexus, not in the spinal cord. In other words, it should be considered a peripheral and not a central lesion, as in poliomyelitis. Even if we disregard the sensory symptoms, neither the etiology nor the condition of the bone changes speak for the latter. In poliomyelitis of long duration the bones of the affected limb are thin and smooth, and are deprived of their anatomic characteristics. The bone changes confined to the diaphysis only and sparing the epiphysis, are very well shown in Figure 4, which represents the bone changes in a demented 39 year old patient who was paralyzed in both lower limbs for thirty-seven years. This also followed a fall. Not only the bone changes but also the entire clinical picture in this case⁶ were totally different from the case reported in this article.

Clinical Notes, Suggestions, and New Instruments

VERRUCAE

REPORT OF A CASE

WILLIAM ALLEN PUSEY, M.D., CHICAGO

This case in an Italian boy is interesting, both on account of the excessive number of warts, and the result of the application to them of Vlemminckx's solution.

The young man appeared at my office for treatment, September 3, at which time a photograph (Fig. 1) was made. He had a crop of warts that were literally confluent over nearly all of the forehead and temples, and were scattered in large numbers over the rest of the face. The photograph, unfortunately, because of the bad lighting, does not give an adequate idea of the abundance of the lesions. They were as abundant, and as prominent, over the entire forehead as they appear on the right side in the photograph. They made, in fact, a continuous patch three fingers wide below the hairline over the whole forehead. The patient had also a large crop on the backs of his hands.

He was given a solution of 1 part of Vlemminckx's solution and 3 parts water, which he applied once daily to the face and hands. In a week he returned. There was a slight scaling dermatitis from the Vlemminckx's solution, and a remarkable decrease in the warts. He continued the application, and returned again nine days later. At that time the warts on his face had almost entirely disappeared. His condition at this time is shown in Figure 2, taken sixteen days after the first photograph.

Fig. 1.—Appearance of warts on the day the patient presented himself for treatment.

The warts on the hands, which individually were larger, had not completely vanished, but many of them were gone, and all of them were flattened down and manifestly involuting rapidly.

My attention was first called to the use of Vlemminckx's solution in connection with verrucae by the late Dr. James Nevin Hyde. I have used it in a desultory way for many years without being impressed with its value. Lately I have

been using it in stronger solutions and with interestingly good results. I have never seen another case in which removal of the lesions was so surprising as in the one described above, but the solution has served me well in many

Fig. 2.—Appearance of the patient sixteen days after he first presented himself for treatment.

of these troublesome cases. The method of application that I have found most effective is to put on a small dressing, just a little larger than the wart, wet with full strength Vleminkx's solution, and held in place by adhesive plaster. This is left on over night, and repeated until irritation is produced; then it is used less frequently until the wart disappears, or until, in case of plantar warts, the desiccated horny mass can be dug out.

A NEW METHOD FOR PROCURING BLOOD FOR WASSERMANN TESTS*

R. G. OWEN, M.D., AND F. A. MARTIN, M. D., DETROIT

For the past three years we have drawn bloods for Wassermann tests with a special instrument which we have found convenient and economical.

As shown in the accompanying illustration, it is a small metal cap which fits the centrifuge tube into which the blood

Instrument for drawing blood for Wassermann test.

is drawn. The sides of the cap are flexible so that it will fit tubes of varying sizes within a moderate range.

A needle without a hub is sterilized by dry heat in a small test tube with the point of the needle down. When ready for use the needle may be removed without touching the point. It is held by the middle, the wire withdrawn and the butt end of the needle is inserted into a hole in the top

of the cap and tightened with a set screw. The cap is placed on the sterile centrifuge tube, and the instrument is ready for use.

With this instrument, the tube and cap furnish a good handle, and the needle is held rigidly so that it may be guided accurately. The hole in the cap is made large enough to hold any size needle up to and including an 18 gage.

In our work we use thick-walled centrifuge tubes, without a lip, whose outside diameter is approximately 16 mm. The needles used are either 18 or 20 gage. They may be purchased in gross lots for slightly less than five cents each.

After use, the needle is dropped in a strong soap solution from which it may be cleaned with alcohol and ether, resterilized, and used many times.

When the needles and tubes are sterilized in large lots, numerous bloods may be drawn within a very short time and at a slight cost, particularly if the needles are cleaned and used again.

These instruments may be obtained from the Central Scientific Company of Chicago.

33 East High Street.

FORCEPS FOR USE IN PLACENTA PRAEVIA

W. B. HANBIDGE, M.D., OGOENSBURG, N. Y.

The patient on whom these forceps were first used was at term but not in labor. She had a rather profuse hemorrhage while in bed at 3 a. m., Aug. 11, 1919, and was sent to the hospital with a diagnosis of lateral placenta praevia. Examination revealed a very rigid cervix which admitted the index

Forceps for use in placenta praevia.

finger. The placenta was felt to the left about one-half inch from the os. An anesthetic was given and the cervix dilated to the extent of slightly over an inch. There was some hemorrhage during dilation. A pair of forceps had been prepared by cutting off the posterior part of the fenestra of each blade of a pair of obstetric forceps close to the shank, and at the point where the anterior portion curves backward. In using these forceps, the left blade was turned with the concave surface to the pubes. The handle was held well to the right of the operator and the point pushed up within the uterus, the handle at the same time being carried well to the left and back to the perineum. At the same time the assistant pressed on the fundus of the uterus to hasten the discharge of liquor amnii, and to keep the head well down. The right blade was introduced by reversing the movements. The forceps locked easily and gripped the head firmly. Gentle traction was applied, and all oozing of blood ceased. The anesthetic was removed, and gentle traction was kept up by tying a roller bandage tightly around the handles and extending it over a rod, at the foot of the bed, which could be elevated or lowered by being attached to the irrigating stand. A 2½ pound weight which was tied to the end of the pendant strip of bandage was all the traction that seemed necessary. Occasionally the weight was removed for a short time so that there would not be a continuous pressure of the forceps on the scalp. Pains came on promptly, and at the end of five and a half hours the cervix was about three-fourths dilated. As the presentation was a left occipitoposterior one and the head was not descending, the placenta praevia forceps were removed and obstetric forceps applied. The head was brought down and the occiput rotated to the front.

The infant was normal and uninjured except for a slight cut behind one ear. This may have been done by the obstetric

* From the Detroit Clinical Laboratory.

forceps, but it was probably caused by the placenta praevia forceps on account of no axis traction attachment being used, the blade being too sharp in front and the position being left occipitoposterior.

In this case the placenta praevia forceps were very easily applied, and the pains came on at once and at short intervals. The forceps seemed to act as a gentle dilator of the cervix to stimulate uterine contractions, and a slight amount of traction kept up sufficient pressure of the head on the placenta to prevent hemorrhage.

In modifying a pair of obstetric forceps, it would be preferable to have one with a lock that allows the shanks to come closely together, as it can be applied through a smaller opening than one made with the English lock.

A NEW FRAME FOR TUBERCULOSIS OF THE SPINE

GORDON N. MORRILL, M.D., CLEVELAND

The rather general acceptance of the Whitman-Bradford frame as the best appliance for hyperextension of tuberculous spines leads me to describe a frame which in my experience has proved superior to it in every way for treatment of this disease in children.

The principal reasons for dissatisfaction with the Whitman modification of Bradford's appliance are obvious to those who have had experience with it, namely: (1) the impossi-

Fig. 1.—Above, Bradford foundation with the new support attached; below, top view of frame.

bility of holding the kyphos up, owing to the inevitable sagging of the canvas; (2) difficulty in ascertaining the position of the kyphos after the child is strapped into place, because of the thick padding underneath; (3) the necessarily tight apron holding the patient in position, with the result that not only is breathing made difficult, but the body is flattened and compressed to such a degree that normal development is impossible; (4) bad ventilation caused by direct bodily contact with the canvas cover and rubber sheeting; (5) the fact that the entire frame must be bent to the corrective angle, and (6) the great danger of genu recurvatum, owing to the rigid fixation of the knees in a hyperextended position.

Each of these defects is completely eliminated in a frame devised by Dr. H. O. Feiss and myself. For eight years I have used it exclusively in all acute cases of dorsal and lumbar tuberculous spines in my work at Lakeside and Rainbow hospitals, with unvarying success and the increasing conviction that it is the most practical device I have yet seen for the purpose.

Because of these excellent results, I feel justified in going considerably into detail in describing the frame and the part it plays in the treatment of Pott's disease in children.

The appliance is constructed on the Bradford frame foundation, which need be made in but two sizes for children under 12. Fastened to the sides of the gas-pipe frame is the support-unit of the device, and this may be moved to

any desired position by adjusting four screws holding the cross bars in place (Fig. 1). The support proper is composed of two curved pieces of steel fastened to the cross bars $1\frac{1}{2}$ or 2 inches apart, leaving sufficient space for the spinous processes. To each side of this support proper is attached one-half the waist band, which serves, not as a means of confining the patient, but of fixation for the perineal and shoulder straps. These are attached as shown in

Fig. 2.—Child in position on the frame, showing the arrangement of accessories.

Figure 2, and buckled firmly in place. The knee strap, it should be noted, is placed well above the patellae, thus eliminating the danger of pressure at a sensitive point. An important item, also, is the pad under the knees (Figs. 2, 4, etc.), to prevent stretching the posterior structures of the knee joints. Strips of felt are used as padding on the spinal support and waist-band; and canvas covers, as well as overslips of finer material, are laced on the ends of the frame. A space is left between the lower of these and the support-unit for the use of the bed-pan, for which the entire frame should be raised on blocks. The child wears shirt and drawers when put on the frame, and the outer garment may be buttoned beneath the support, making it unnecessary that the clothing be so large as to include the entire apparatus.

The many advantages of the frame I have described are easily recognized. Naturally, the convex curve of the two pieces of steel, which may be quickly adjusted for any degree of kyphosis, is the main corrective agent of the device. It tends to restore the normal curve of the spinal column, through exaggerating it to compensate for the deformity. By hyperextension of the spine, and by the rigid convexity of the support, the body weight, pulling in opposite directions, separates the diseased vertebrae—which in itself has a naturally curative effect—and at the same time reduces the kyphos. There is no weight or pressure to flatten the chest or abdomen; therefore, normal development and the body metabolism are not interfered with—facts which are made evident by the increase in weight which has always occurred in these cases.

The raising of the trunk above the frame not only makes good ventilation, but also enables the visiting physician

Fig. 3.—Patient having tuberculous spine and hip, with traction on limb.

instantly to ascertain the position of the kyphos in relation to the support.

Moreover, traction may be used without interfering with the patient's position on the frame, as in Figure 3, in which the boy is being treated simultaneously for tuberculosis of the hip and of the spine. In such instances, the frame should be tied at its upper end to the head of the bed, which, together with the perineal straps, makes slipping downward

impossible. In one case, a child having complete pressure paraplegia with paralysis of the bladder and bowels was so treated, with traction on the legs, and in three weeks the paralysis had practically disappeared.

If this frame is to be used on a bed, it is advisable to put a board under each end to prevent the bed's sagging. But it may be laid on a table quite as well (Figs. 2, 4 and 6).

Beyond seeing that the support fits the deformity, there is little to be done for the patient while on the frame, except that he must be rolled off carefully once every day, and his back bathed with alcohol and powdered with zinc oxid. While this is being done, the child should always take a position resting the elbows on the table, the chin in the hands (Fig. 5), thus keeping the spine in hyperextension until the apparatus is again in place. In rolling the patient both off and on the frame, the nurse places her hand on the chest with her arm supporting the abdomen, and turns the frame with the child. To this treatment and proper adjustment of the support is due the fact that there has never been a pressure sore in my experience with the appliance. If the pressure is correctly applied, there will be merely a slightly reddened area on each side of the kyphos. However, it must be clearly understood that this device is never to be used with adult patients, as their skin cannot withstand the pressure of the proportionately greater body weight without resulting abrasions.

With caries of the bodies of the vertebrae it is absolutely essential that the patient be kept on the frame at least six months, as the spasm of the erector spinae seldom ceases under that period. Even if this were not true, a shorter

Fig. 4.—Examples of the two sizes of frame used for children under 12; the pad under the knees is important.

Fig. 5.—Position to be assumed by patient daily while the back is being cared for.

period of recumbency would be unwise, owing to the probability of an exacerbation of the disease. Frequently, as much as a year is required to make certain the best results. Lateral roentgenograms and tracings of the kyphos should be made every two months while the patient is on the frame, increasing the tracings to one a month when the patient has been removed and fitted to a suitable brace. Only in these

ways can reliable data on the progress of the disease be secured.

For treatment of tuberculosis of the upper dorsal spines, I use the same frame with a specially adapted support-unit. It differs from the one described only in the curve of the two steel bars, which in this case are bent into a figure S (Fig. 7). With the high point of the curve under the

Fig. 6.—Patient in Figure 5 in place on the frame.

Fig. 7.—Above, special device for tuberculosis of the upper dorsal region (note arrangement of straps and padding); below, patient in position on frame.

kyphos, the weight of the head acts as traction, and usually secures all the extension needed. This is much better than the commonly used plaster bed, owing to the complete ventilation secured, and the ease with which its curve may be adjusted.

In spinal, as in all forms of tuberculous disease, the open air treatment is of vital importance. Therefore, one of the extremely practical features of the device is the ease with which it may be carried about by the nurse in the hospital or the parent at home. The child may even be brought to the physician's office without removal or danger of displacement.

The accompanying photographs cannot fail to make more evident the points I have endeavored to emphasize, particularly the patients' invariable well-being and their normal bodily development while recumbent.

It is with the hope that this appliance may prove of value to others who are interested in the treatment of tuberculous spines that I present it for consideration.

429 Osborn Building.

Treatment of Mental Disorders.—In every large center of population a department for nervous and mental cases should be provided in connection with the best general hospital. This department should be so organized and equipped that the patients would be treated by the most approved methods at the hands of specially trained and experienced nurses and physicians. In no class of case is the necessity for specialists more pressing. In fact special knowledge and skill are the only sure safeguard against gross neglect and mismanagement in the treatment of mental cases.—W. L. Russell, *Canadian J. Mental Hygiene* 1:161 (July) 1919.

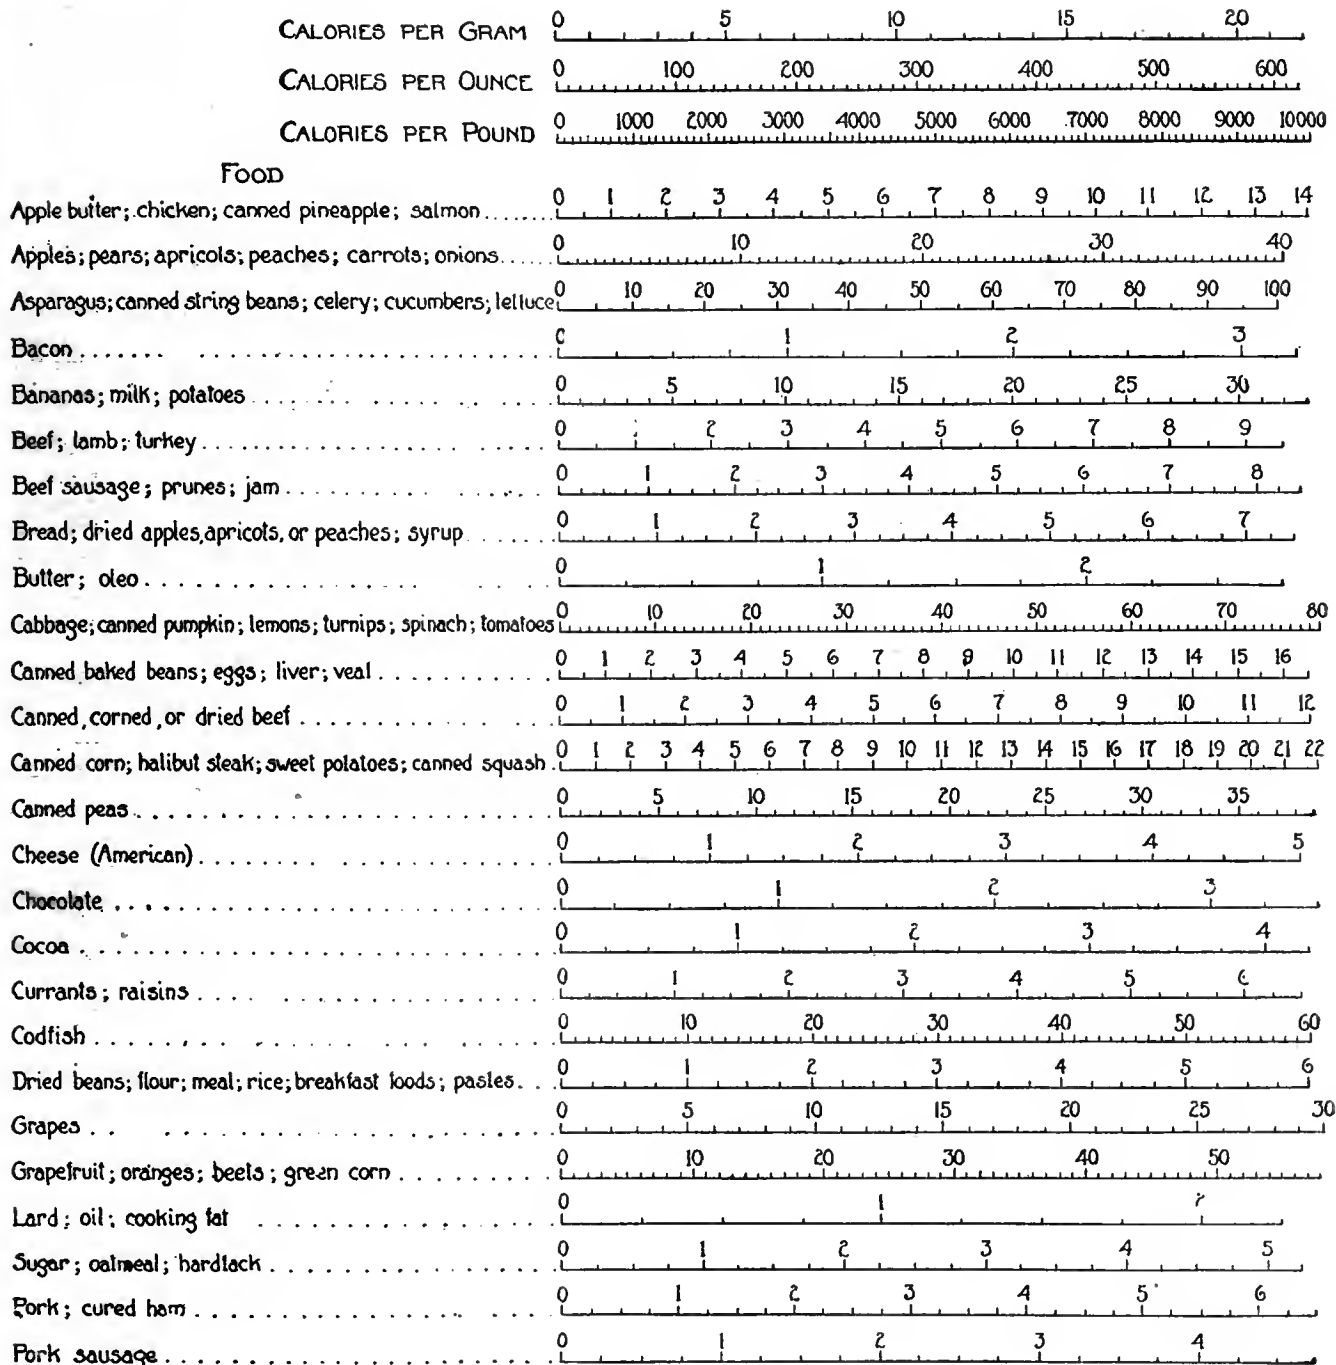

A CHART FOR RAPID CALCULATION OF CALORIFIC
VALUES OF DIET

J. F. McCLENDON, Ph.D., MINNEAPOLIS

Associate Professor of Physiology, University of Minnesota
Medical School

The accompanying chart furnishes the calorific value per unit weight and performs simultaneously the process of multiplication and division, thus giving an immediate answer

calculation often exceeds the savings that may arise therefrom. The object of the chart is to reduce the labor of calculation to a vanishing quantity. The time required to use the chart decreases with practice, but is so small as to be negligible even the first time the chart is used. The first time I used the chart, five minutes were required to calculate the calorific value of a diet containing seventeen articles of food, and the error was only 5 per cent. The error due to variation of the foodstuff may be 5 per cent. or

Scale for rapid determination of calories.

to the question of the calorific value of any diet, bill of fare or store of food. It is one thing for the physician to recommend a more adequate diet for a patient suffering from pellagra, tuberculosis or other disease, but quite another thing for the patient to procure such a diet. With the increase in cost of food, economic rationing becomes more and more desirable. The calculation of the calorific value of food is seldom done as an economic measure, since the cost of such

more, and hence the use of the chart in calculation is open to no more criticism than the use of Atwater and Bryant's data for the composition of food.

Since food is usually purchased by the pound or in containers whose capacity in pounds is known, the use of the pound as the unit of weight is most convenient. Besides the chart, a measuring tape is necessary. A millimeter tape is most convenient if it is remembered that each millimeter

represents 100 calories, or each centimeter, 1,000 calories. The "calories per pound" scale at the top of the chart represents a millimeter tape with the calory units marked on it, and it may be cut out or copied for use, but it is not long enough and should be extended. A fine thread may be used in conjunction with the "calories per pound" scale, as in the ordinary practice of measuring with a string and transferring to a rule.

A list of the foods and their weights in pounds is prepared. Beginning with the first food on the list, the scale opposite its name on the chart is found and the number corresponding to its weight is noted on the scale and the distance from this number to the left hand end of the scale is measured with the tape. The part of the tape used in this measurement is marked off by covering it with the left thumb, the next succeeding portion of the tape is used to measure the second article of food, and at the end of the process, the calorific value of the whole list of foods is read off directly from the tape. For instance, let us suppose that we wish to calculate the total calorific value of 1 pound of bread and 10 pounds of apple butter. Using the millimeter tape measure (which is identical with the "calories per pound" scale at the top of the chart) we measure off one unit of the bread scale and find it to be 13 mm. Then, taking the same measure and commencing at the 13 mm. point we measure 10 units on the apple butter scale. We shall find that this will take us up to about 84 mm. Therefore, the total calorific value of the 1 pound of bread and 10 pounds of apple butter are 8,400 calories. There may be an error in calculation of 20 calories, which is only 0.5 per cent. Of course, in rapid work, ten times as great an error may occur.

Some further examples are as follows: Suppose a meal is made of 1 pound of beef and 1 pound of potatoes. We measure the beef as about 10 mm. and the potatoes as about 3 mm., or a total of 13 mm. or 1,300 calories (whereas the correct calculation is 1,307 calories by multiplication and addition). Besides this slight error in calculation there is a much greater error in using an average figure for beef. If we were calculating the beef used in an army mess, the data would be nearly correct; but when the beef is cut up there is considerable variation in the different cuts, as illustrated by the fact that Atwater and Bryant devote ten pages of tables to data on fresh beef. Since the different cuts vary from 125 calories per pound for very lean neck to 2,440 calories per pound for very fat flank, it might seem useless to use the chart for beef at all. In case of the higher calorific values, most of the calories are due to large masses of fat that would not be eaten as such, and the lower calorific values are due to the presence of much bone that makes the cuts fit only for soup. In the ordinary practice of eating steaks and chops, the average figure for beef would not be very far wrong. If we have a different scale for every cut of beef, the chart would be too large for ordinary use.

As another example, suppose we make a pudding of a dozen eggs, 5 pints of milk and half a pound of sugar. A dozen eggs weight approximately $1\frac{1}{2}$ pounds, and 5 pints of milk 5 pounds. We find that eggs have the same calorific value as canned baked beans, and milk the same as bananas, to remember which will aid in finding the scale. We measure off 1.5 units on the egg scale and find it to be 9 mm., and 5 units on the milk scale and find it to be 15 mm., or a total of 24 mm., and half a unit on the sugar scale and find it to be 9 mm., making a grand total of 33 mm., or 3,300 calories. The correct calculation gives 3,317 calories; hence our error is about 0.5 per cent.

If the food has been weighed in ounces, the same chart is used, but a new measuring tape must be prepared by cutting out or copying the "calories per ounce" scale at the top of the chart. For instance, to find the calorific value of 1 ounce of butter we measure one unit on the butter scale with our new tape and find it to be 217 calories, whereas the correct calculation gives us 217.38 calories.

If the weight of the food is recorded in grams, the same chart is used, but a third form of measuring tape is prepared by cutting out or copying the "calories per gram" scale at the top of the chart. For example, to find the calorific value

of 1 gm. of butter, we measure one unit on the butter scale with this third form of tape, and we find it to be 7.7 calories, whereas the correct calculation would give us 7.668 calories.

In case the food is not sold by weight, the capacity of containers may be estimated. The volumetric capacity of containers may vary if not fixed by law, and the gravimetric capacity may vary with variation in the character of its contents. The tabulated data, obtained in San Francisco, may be of some use. The weights are net.

ESTIMATED CAPACITY OF CONTAINERS

Apples	40 lbs. per box (135 apples in a 4-tier box).
Bananas	70 lbs. per bunch.
Beets	10 lbs. per dozen.
Cantaloupe	65 lbs. per crate.
Cassaba melon	40 lbs. per crate.
Carrots	80 lbs. per sack.
Cauliflower	40 lbs. per dozen.
Celery	3 lbs. per bunch.
Cucumbers	40 lbs. per lug-box.
Corn (green)	70 lbs. per sack.
Eggs	54 lbs. per case, $1\frac{1}{2}$ lbs. per dozen.
Grapes	45 lbs. per lug-box, 40 lbs. per crate.
Grapefruit	65 lbs. per crate (64 grapefruits).
Lemons	70 lbs. per crate (350 lemons).
Lettuce	40 lbs. per crate, 13 lbs. per dozen.
Milk	2 lbs. per quart.
Oranges	70 lbs. per crate.
Peaches	55 lbs. per lug-box, 40 lbs. per pony-crate.
Potatoes (sweet)	118 lbs. per box.
Radishes	7 lbs. per dozen bunches.
Spinach	10 lbs. per dozen bunches.
Tomatoes	55 lbs. per lug-box.
Turnips	80 lbs. per sack.

The weight of contents of canned and dry package goods is marked on the container. The foods sold by volume and not weight are usually of low calorific value, and hence the absolute error in estimating the weight is very small.

AND OTHER REMEDIES IN THE TREATMENT OF DISEASE.

USE AND ABUSE OF CATHARTICS*

(Continued from page 30)

THE CATHARTIC SALTS

"Taking a dose of salts" is generally considered an easy and simple way of producing an evacuation of the bowel. Consequently few medicaments are more generally used—and abused—by both physicians and laymen than are the saline cathartics. These salts, in fact, belong among the habit-producing drugs, and are responsible for a large proportion of cases of cathartic habit. That they are occasional accessory causes of death from ileus and appendical and other forms of peritonitis is only too well known to the surgeon.

The chief effect of the salines is to interfere with the absorption of some of the ingested water, so that it is eliminated into the stool instead of passing through the system. They do this, presumably, because they are practically nonabsorbable in the alimentary tract and therefore retain enough water in the colonic contents to render them isotonic with the blood.¹

As an isotonic solution of sodium sulphate is 2 per cent. of the dried (4 per cent. of the crystalline) salt,

* This is the thirteenth of a series of articles on the pharmacology, physiology and practical application of the common laxatives and cathartics. The first article appeared October 18.

1. Other theories have been advanced to explain the action of these agents. Space for the discussion of these is not taken here, as they do not influence their use.

it would take 500 c.c. (1 pint) of fluid to carry out of the system a dose of 10 gm. ($2\frac{1}{2}$ drams) of this salt. In case of magnesium sulphate, 7.5 per cent. of which is isotonic, the proportion of water abstracted is somewhat greater, because this substance is converted in the intestine into magnesium bicarbonate and sodium sulphate, both of which are soluble and practically nonabsorbable. Evidently this is why magnesium sulphate is a more efficient purgative than sodium sulphate. Magnesium citrate, on the other hand, yielding sodium citrate and magnesium bicarbonate, is proportionately less powerful than magnesium sulphate, to the extent that sodium citrate is a feebler cathartic than sodium sulphate.

ILL EFFECT ON THE STOMACH

When the salts are ingested in any other than isotonic strength, they are rendered isotonic in the stomach. In case of strong salt solutions, this is accomplished at the expense of delayed evacuation of the stomach and irritation of the gastric mucosa. We may, therefore, formulate the rule that *salines should be given in dilute solution—generally, a teaspoonful to a tumblerful of water—unless abstraction of fluid from the system is aimed at.* The gastric distention produced is by no means advantageous to the functions of the stomach. This is so well known that purgative salts are preferably taken on an empty stomach; their ingestion is so timed, that they have largely left the stomach before food enters it, which is ordinarily accomplished by giving them at least half an hour before meals. This presupposes, however, a normal emptying time of the stomach. When there is gastric motor insufficiency—a condition in which fluid is evacuated with difficulty and therefore interferes with digestion—these agents are, as a rule, not well tolerated. The condition of sufferers from gastritis is likewise aggravated by any but most moderate doses of isotonic alkalinized solution. When there is nausea or vomiting, these agents, with the exception of magnesia, cannot be administered, for they have a tendency to provoke nausea and vomiting in sensitive persons. These are the reasons that most of the cathartics of this class are practically taboo with the gastro-enterologist, who deals with so many of these patients. Even their transduodenal administration by means of Jutte's tube has recently been advocated, to spare the stomach the action of these chemicals.

EFFECTS IN INTESTINE

While these bodies delay the evacuation of the stomach when they are given in concentrated solution or when they produce diarrhea, the moment they enter the intestine they hasten the onward progress of its contents, producing a liquid evacuation within from one to four hours of their ingestion. Such prompt effect is dependent, however, on good peristaltic activity. When this is deficient, as is likely to occur in those confined to bed, instead of one prompt and comfortable bowel movement in one, two or four hours, several small bowel evacuations may ensue with considerable griping in the course of twenty-four hours. For this reason the salines may be advantageously combined with peristaltic stimulants, as salts and senna, sulphur and cream of tartar. From what has been said it is evident that the best time for giving these salines is in the morning before breakfast: while administering them last thing at night is least likely to produce desirable results.

The rush of fluid through the intestine, induced by saline cathartics, results in a veritable washing out of the bowel, which cannot, however, be complete. Liquid and solid materials are passed along the intestine by different processes. While the rhythmic segmentation movements of the intestine may cause a rapid passage of fluid, solid contents, which depend for their propulsion on peristalsis, may be left behind. While the artificial diarrhea produced may carry away poisons, it also causes the loss of a certain amount of nutriment. On the latter action is based their use in the treatment of obesity, which, however, is not nearly as rational as diminution in the intake of nutriment. Not much can be said in favor of their action in so-called intestinal autointoxication: for, while they may remove some of the bacteria and the poisons produced by them, the fluidity of the bowel contents and the greater amount of organic matter contained in them may favor the more rapid growth and development of those organisms left behind.

The evacuant action of the salines is chiefly useful when a single flushing out of the bowel is desired to remove, as thoroughly as possible, irritant or otherwise offensive material. As they produce but little irritation in the intestine, they may be used even in the presence of enteritis and in dysentery. Salines are the classical evacuants to be used in connection with mercurials and anthelmintics, and in case of poisoning.

One of the chief faults of the cathartic salines is their deficiency in stimulating peristalsis: indeed, intravenous or intramuscular injection has been shown to inhibit bowel movement. The rapid evacuation produced is due to distention of the intestine with fluid; and this is so marked that salines are particularly obnoxious for preoperative purgation or for evacuation of the bowel prior to a roentgenologic examination of the abdomen. They are contraindicated in chronic atonic constipation, as they not only do not antagonize the underlying pathologic condition, but actually aggravate it by lessening the need for peristaltic activity, as liquid contents are more easily propelled than solid material. Their use in dyschezia (torpor recti) is irrational, as in these cases they act no better than an equivalent amount of water injected by rectum; and it surely is not good sense to upset water absorptive and other physiologic processes all the way down the alimentary canal in order to distend its lowest segment with fluid that might so much more readily and efficiently be introduced from below.

The chronic use of salines is justified only in those cases of constipation due to minor colonic stenosis, even cancerous, and to partial anatomic obstacles (adhesions, etc.) in patients for whom surgical relief is not desirable.

SYSTEMIC EFFECTS

The source of the fluid eliminated in the stools in the course of saline catharsis is chiefly ingested water. Even if the saline is not taken in isotonic solution, enough water is ordinarily consumed in our diet to produce isotonicity without abstraction of fluid from the blood. It is only when dry diet and concentrated salt solution are used simultaneously that abstraction of fluid from the system occurs. As a result of such concentration, the red blood count may rise to 7,000,000 per cubic millimeter, to return to normal within the next few hours even if no fluid has been taken. A second less marked rise in the concentration of the blood may be observed during the stage of diuresis.

Alongside of this temporary diminution in the volume of circulating fluid there is a tendency to depression of the circulation. This accounts for the feeling of faintness experienced by feeble individuals at the height of action of these agents, as well as for the relief of headaches due to cerebral hyperemia or high blood pressure testified to by others.

In treatment of dropsy, the cathartic salines are perhaps the least harmful among the hydragogues, owing to absence of intestinal irritation. However, their unfavorable action on the stomach may render jalap or elaterin preferable in certain cases. When given for this purpose, from 15 to 30 gm. ($\frac{1}{2}$ to 1 ounce) of sodium sulphate (preferable to magnesium sulphate for reasons to be given below), dissolved in from 30 to 60 c.c. (1 to 2 ounces) of water, are taken on an empty stomach, best in divided doses every fifteen minutes until all has been taken. It would be poor therapy, however, to force a patient to take this disagreeable potion, obnoxious not only to the palate but also to the stomach, unless moderate drink restriction is practiced at the same time. The policy of this therapy may be questioned when we realize that mere drink restriction could produce the same result, as far as dehydration of the system is concerned, in a more gradual and less disturbing manner. There are a number of other weighty objections to it. Thus, the salines fail to produce their purgative effect as soon as a certain degree of systemic dehydration has occurred. Under such circumstances they are absorbed; and, if they cannot be promptly thrown out by the kidney, must be retained with an adequate amount of water to maintain isotonicity, thus still further adding to the waterlogged condition of the patient. Furthermore, in the dropsy of myocardial insufficiency, the weakening of the patient by the routine administration of heroic doses of salines more than offsets the benefit to be derived from the abstraction of the small amount of fluid lost in this way. In patients with enfeeblement of the circulation, the drastic use of salines, so commonly practiced, cannot be too strongly deprecated. All this accounts for the observation made, at times, that a patient who at first seemed to improve on this treatment becomes more dropsical again on its continuance. All that can be said in favor of it is that a dropsical patient should not be permitted to become constipated; and that the gentle use of salines, enough to produce one or at most two liquid stools a day, might be recommended, alongside of moderate drink restriction. When watery bowel movements do not result, the administration of the saline should be stopped.

A note of warning should furthermore be sounded against the use of magnesium salts when there is a suspicion that they might be absorbed instead of being thrown out with the stools, as might occur not only under conditions just described, but also in case of ileus. If the patient cannot get rid of the dose in the usual way, it may, by its absorption, aggravate the existing intoxication and even contribute to a fatal result by the depression of the respiratory center and the curare-like action on muscles inherent in the magnesium ion. An extraordinarily high specific gravity of the urine (even 1.070 or 1.080) is suggestive of magnesium sulphate poisoning. In such a case, the antagonism between calcium and magnesium, demonstrated by Meltzer, might be of practical importance, as well as the hypodermic use of 0.6 instead of 0.9 per

cent. salt solution to lessen the prevailing excess in osmotic tension. Sodium sulphate is much safer under these circumstances, as it would be less poisonous if absorbed.

One may well be skeptical that anything can be accomplished by saline catharsis in the way of diminishing the bulk of exudates, such as those of pleurisy with effusion. The most that can be said for the practice is that salines, in moderate doses and given in fairly concentrated solution, may be preferred to other cathartics to antagonize constipation. Exhausting purging is a display of poor judgment in these cases, as it can only do harm.

To reduce milk secretion in weaning or to lessen engorgement of the breasts in an otherwise healthy woman, drink restriction may be accompanied by use of saline cathartics for a day or two.

(To be continued)

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

CHINOSOL.—Oxyquinolin Sulphate.—(C_9H_7ON) $_2H_2SO_4$.—A normal oxyquinolin sulphate.

Actions and Uses.—So far as experimental evidence and experience go, chinisol is non-toxic. It is a powerful antiseptic, somewhat stronger in this respect than mercuric chloride and considerably stronger than phenol. It has been found to exert an antiseptic action in solutions containing 1 part to 10,000. It is a feeble germicide, being weaker than phenol and much weaker than mercuric chloride. It is incompatible with alkaline substances (soap) and with salts of mercury and iron. Chinisol does not coagulate albumin or injure the mucous membranes or tissues. The sensitiveness of patients to its solution varies considerably. In some it produces a pronounced stinging when applied to mucous membranes even in dilute solutions (1 to 2,000), but it is claimed not to cause harmful irritation in any strength. It is claimed to possess marked analgesic power and to be an efficient deodorant.

Dosage.—For internal use 0.3 Gm. (5 grains) three times daily. As an antiseptic the average strength of solution used is 1:1,000; as a nasal spray or douche 1:3,000; as a gargle 1:2,000, and as an eye-wash 1:4,000, gradually increased in each case according to the tolerance of the patient up to 1:500. In gargles the strength may be increased to 1:250. As a vaginal douche the initial strength used is 1:1,000, increased to 1:100 if necessary.

Manufactured by Chinisol Co., Parmele Pharmaceutical Co., New York. U. S. patent No. 906,918 (Dec. 15, 1908; expires 1925). U. S. trademark No. 28,750.

Chinisol Tablets.—Each tablet contains chinisol $\frac{1}{4}$ Gm.

Chinisol is a yellow crystalline powder of saffron-like odor and burning taste. It melts at from 175 to 177.5 C. It dissolves readily in water, but with difficulty in alcohol and it is insoluble in ether. The aqueous solution has an acid reaction.

A drop of solution of ferric chloride produces in a solution of chinisol a marked green coloration. Barium chloride produces a white precipitate. Solutions of alkaline hydroxides precipitate from an aqueous solution of chinisol a white precipitate, consisting of interlaced crystalline needles, which, after filtration, washing and careful drying in a desiccator, should melt at from 73 to 75 C. On incineration chinisol should not leave a weighable residue.

DUBOIS' IODOLEINE.—Iodized Poppyseed Oil.—An iodine addition product of poppyseed oil.

Actions and Uses.—Dubois' Iodoleine may be used whenever iodides are indicated, its effect being more gradually exerted. See general article, Iodine Compounds for Internal Use, N. N. R., 1919, p. 143.

Dosage.—From 0.25 to 2 Cc. (0.3 Gm. to 2.5 Gm.) per day in capsules taken at meals of Dubois' Iodoleine containing 33

per cent. of combined iodine by weight. From 1 to 10 Cc. (1.14 Gm. to 11.4 Gm. of Dubois' Iodoleine containing 26 per cent. of combined iodine by weight injected intramuscularly when intensive action is desired. Warm to body temperature before injection. For oral administration Dubois' iodoleine is supplied in the form of capsules. For intramuscular administration it is also supplied in ampules.

Manufactured by Laboratoires Dubois, Paris, France (David B. Levy, New York, distributor). No U. S. patent or trademark.

Dubois' Iodoleine Capsules, 0.25 Cc.—Each capsule contains 0.3 Gm. Dubois' iodoleine equivalent to 0.10 Gm. iodine.

Dubois' Iodoleine, Injectable.—100 Cc. contain 30 Gm. iodine.

Dubois' Iodoleine, Injectable, Ampules, 1 Cc.—Each ampule contains 1 Cc. of sterile Dubois' iodoleine equivalent to 0.3 Gm. of iodine.

Dubois' iodoleine is an oil-like liquid, lightly brownish, with an odor of poppyseed oil. It is insoluble in water or alcohol, soluble in chloroform and in ether.

Specific gravity of Dubois' iodoleine 30 Gm. per 100 Cc. at 15 C. is 1.14. Specific gravity of Dubois' iodoleine 40 Gm. per 100 Cc. at 15 C. is 1.22.

When heated it chars and gives off purple vapors of iodine. When heated with alcoholic potassium hydroxide, Dubois' iodoleine is saponified and the iodine changed to potassium iodide.

About 1.5 Gm., accurately weighed, is saponified by boiling with 100 Cc. half-normal alcoholic potassium hydroxide for three hours under a reflux condenser. The condenser is then removed and the alcohol evaporated. The residue is then acidulated with diluted nitric acid, a small amount of sodium sulphite is added to prevent oxidation of iodine. The fatty acids are then removed by filtration or extraction with chloroform and the iodide determined by titration with potassium thiocyanate, using ferric ammonium sulphate as indicator.

By this method the iodine in Dubois' iodoleine capsules is not less than 40 Gm. in 100 Cc., and in Dubois' iodoleine injectable not less than 30 Gm. in 100 Cc.

THYROXIN.—4,5,6-trihydro-4,5,6-triiodo- α -oxy- β -indole proprionic acid ($C_9H_7OIN_3$). C_7H_4 .COOH; an active principle obtained from the thyroid gland. It contains 65.1 per cent. iodine.

Actions and Uses.—Thyroxin is used essentially for the same purposes as Dried Thyroids, U. S. P. It is indicated in cases of diminishing or absent thyroid functioning such as simple goitre, cretinism and myxedema. The reports of Kendall show that thyroxin affects the pulse rate, blood pressure, nitrogen metabolism, relieves symptoms of myxedema and will produce hyperthyroidism. According to Kendall's view the emphasis for the activity of the thyroxin molecule should be placed on the oxy-indol nucleus rather than on the presence of iodine. The most important quantitative measure is the determination of the basal metabolic rate. One milligram (0.04 Gm.) of thyroxin increases the basal metabolic rate in adults approximately 2 per cent. The relation holds for larger amounts, that is, 10 milligrams increases the metabolic rate 20 per cent. It is through the basal metabolic rate that the pharmacological action of thyroxin can be followed best. When given by mouth or intravenously, there is no immediate effect except occasionally when an increase in pulse rate and respiration occurs, which, however, will soon disappear. After twenty-four to thirty-six hours there is a noticeable increase in pulse rate. There may be loss of weight and beginning of nervous manifestations. If the dosage is continued for five or six days, the typical so-called hyperthyroid symptoms will be produced: loss of weight, increased pulse rate with tachycardia, nervous manifestations and a sense of fatigue. With small doses the harmful effects are not produced and a stimulating effect is manifest in cases of myxedema. With large doses, the above symptoms are aggravated: the amount of thyroxin required to produce toxic effects is exceedingly small. It has been reported that the maximum effect from a single injection is not reached until the tenth day, the duration of the effects of a single administration of thyroxin being about three weeks.

In some forms of goiter (such as simple adolescent colloid goiter) the function of the thyroid is defective and the administration of thyroxin is indicated; but in most cases of goiter (especially exophthalmic) thyroxin should never be administered.

Dosage.—0.2 mg. to 2 mg. Thyroxin should always be given in minimum doses and in each case the optimum amount should be determined by trial. In general a normal adult will show evidences of hyperthyroidism if given as much as 2 mg. per day. A person afflicted with cretinism requires generally 0.4 to 0.8 mg. per day; a very small cretin requires 0.2 to 1.0 mg. every day or every other day.

In many cases after symptoms of hypothyroidism have disappeared, remarkably small doses suffice to keep the patient in an almost normal state.

The patient should be careful of exertion and should take sufficient protein in the diet to compensate for increased

loss of nitrogen from the action of the drug. Thyroxin is offered in the form of tablets which should be used *only* for oral administration.

Manufactured by E. R. Squibb and Sons, New York, by license of the University of Minnesota. Patents applied for.

Thyroxin Tablets 0.2 mg.—Each tablet contains thyroxin 0.2 mg. (1/324 grain).

Thyroxin Tablets 0.4 mg.—Each tablet contains thyroxin 0.4 mg. (1/162 grain).

Thyroxin Tablets 0.8 mg.—Each tablet contains thyroxin 0.8 mg. (1/81 grain).

Thyroxin Tablets 2 mg. (0.002 Gm.).—Each tablet contains thyroxin 2 mg. (1/33 grain).

Thyroxin was introduced into medicine by Kendall (Kendall, E. C., J. A. M. A., Sept. 14, 1918, p. 872; J. Biol. Chem., December, 1919, p. 265). It is prepared from the thyroid glands of animals by severe alkaline hydrolysis and by precipitation from this alkaline solution of the acid insoluble constituents. Thyroxin is separated from this fraction by treatment with barium hydroxide and subsequent crystallization of the sodium salt from an alkaline solution; it is then further purified by treatment with alcohol containing a weak organic acid. It is presumed to exist in three tautomeric forms.

Thyroxin occurs as white crystalline needles in the pure form. It is insoluble in water and the usual organic solvents. It melts at 250 C. It is very susceptible to reduction being easily decomposed by zinc in alkaline solution. It is decomposed by prolonged cooling in water.

Thyroxin forms salts with solutions of sodium and potassium hydroxides. It also forms insoluble salts of barium and silver.

When thyroxin is treated with alcohol in the presence of mineral acid, it dissolves; this does not occur in the presence of weak organic acids.

Dissolve thyroxin in sodium hydroxide solution; on addition of sodium chloride a disodium salt is precipitated. Add the disodium salt thus obtained to alcohol containing ammonium chloride; on boiling, thyroxin separates in long needles.

On analysis it should yield 65 per cent. iodine.

BARBITAL SODIUM (Sec N. N. R., 1919, p. 83).

Veronal Sodium-Winthrop.—A brand of barbitol sodium complying with the N. N. R. standards.

Manufactured by the Winthrop Chemical Company, Inc., New York. U. S. patent No. 782,739 (Feb. 14, 1905; expires 1922). U. S. trademark.

Thromboplastin Hypodermic-Squibb.—A sterilized extract of cattle brain in physiological solution of sodium chloride. It complies with the description of thromboplastin-Squibb, but a longer time is required for the clotting of blood plasma.

Actions and Uses.—See general article Fibrin Ferment and Thromboplastic Substances (New and Nonofficial Remedies, 1919, p. 117). Thromboplastin hypodermic-Squibb is intended for hypodermic and intramuscular injection to increase the coagulability of the blood.

Dosage.—From 10 Cc. to 20 Cc. every 24 to 72 hours. Thromboplastin hypodermic-Squibb is marketed in 20 Cc. vials which bear an expiration date after which time, the contents should not be used. (The manufacturer reports that no loss of potency could be detected in specimens which had been kept unopened for two years.)

Manufactured by E. R. Squibb and Sons, New York. No U. S. patent or trademark.

Brains from cattle freshly killed are removed under aseptic conditions, using sterile gloves and sterile instruments, and are transferred immediately to sterile containers. They are then taken into a sterile room, connective tissue, blood vessels, etc., removed, and the brain substance is thoroughly ground either in a ball mill or sterile meat grinder. The brain substance is then diluted by the addition of physiological solution of sodium chloride containing 0.4 per cent. triketol in the proportion of eight parts saline solution to one part of brain substance by weight. The reaction of the mixture is then taken, and sufficient sodium hydroxide solution is added to make it neutral to phenolphthalein. It is then filled under precautions insuring sterility into sterile bottles which are stoppered with cotton plugs. The resultant mixture is sterilized by streaming steam for 40 minutes after a preliminary warming. The result is a slightly opalescent, supernatant fluid overlying the coagulated brain substance. It is then tested for sterility, and when required filled into 20 Cc. containers.

Meningitic Form of Acute Poliomyelitis.—When the cervical region of the cord is attacked, one must be on the watch for paralysis of the diaphragm because the virus will not need to spread far to implicate this region. Complete paralysis is easily recognized by the indrawing of the epigastrium with inspiration. When the intercostal muscles are also paralyzed, the condition is pitiable. The child lies cyanosed, with widely dilated nostrils, raising the chest by the accessory muscles. Oxygen gives some little relief, and it is remarkable how long life is prolonged. It is when the paralysis is partial that it may be overlooked, but ineffective cough may rouse suspicion, for in order to cough effectually the diaphragm must be steady.—*Clinical Journal*, December, 1919.

IMPROVED METHODS OF TREATMENT OF SHOCK

Whatever may be the cause or causes of surgical shock—which it would be too venturesome to debate at this juncture—considerable evidence is now available pointing to a loss of circulating fluid.¹ In the early studies of shock, when fall of blood pressure appeared to be the most conspicuous symptom, remedial measures were directed toward inducing the blood vessels to acquire a better tonus in order to restore the efficiency of the circulation. It must be admitted frankly that most of these have failed in general to accomplish anything more than very transitory advantage. Stimulants and vasoconstrictor drugs were naturally first to be tested, and, like related methods of physical therapy, they proved to be of little importance. Subsequently, attention was turned more directly to the impaired volume of the blood in shock, even though no external hemorrhage had occurred. Gasser, Erlanger and Meek² point out, in one of the most recent discussions of this subject, that the blood volume has been found to be decreased in all forms of experimental shock studied and after all grades of damage. They have shown, in common with other investigators, that the effective volume of the blood may be reduced by transudation of plasma, by absolute stasis in some part of the vascular system, by hemorrhage into tissue, especially into the lumen of the intestine, as well as by dilatation of the capillaries and small veins with greatly increased slowing of the circulation.

Consequently, it has seemed logical of late to treat the condition by an attempt to restore the lost fluid to the circulation. The use of isotonic saline solutions for this purpose has proved to be elusive, as the fluid passes out of the vascular system so rapidly that scarcely any gain can be registered. This fact, long known, has led investigators to seek an artificial fluid

that will be more effective in restoring blood volume and maintaining a more normal pressure. The outcome has been the suggestion of various alkaline solutions, and more recently solutions of gelatin³ or glucose.⁴ Mann⁵ of the Mayo Clinic, to whom we owe numerous valuable contributions to the subject of shock, has lately come to the conclusion that the best results in the treatment of experimental shock are obtained by the injection of fluid mediums. The data of the experiments justify the conclusion that none of the artificial solutions give such good results as the use of blood. Mann believes that the so-called colloidal solutions and their various modifications give better results than physiologic sodium chlorid solution, but their potency is certainly not equal to blood or blood serum, and occasionally they might be harmful.

During the war, when the subject of shock came into greater prominence than ever before, many surgeons followed the suggestion of Bayliss⁶ of London and his followers who have used solutions containing acacia for transfusion. This colloid is not readily diffusible, and it is assumed to increase the osmotic pressure of the blood into which it is introduced. Accordingly, the concentration of the blood by transfer of water from it tends to be prevented. For example, whereas after injection of a crystalloid like salt or sugar into the circulation the diluted blood returns to normal volume within a few minutes, this is not the case when concentrated solutions of gum acacia are employed.⁷ When both colloid and crystalloid are introduced in hypertonic solution, it appears that the colloid will hold in the circulation not only the water that it itself slowly attracts, but also the water brought to it rapidly by a hypertonic crystalloid, so that the combined injection of the two results in a rapid and well-sustained expansion of the blood volume. In other words, to quote Erlanger and Gasser, hypertonic gum solutions attract tissue fluids into the circulation very slowly. Hypertonic crystalloids injected intravenously, as is well known, attract water quickly. When the two, the hypertonic gum and the hypertonic crystalloid, are injected to all intents and purposes simultaneously, the gum holds the water that the crystalloid quickly brings into the circulation. Presumably, the blood volume is thus increased by a process that resembles the one which the organism itself employs in combating a reduction in blood volume.

Since the functional collapse of the vasomotor center or of the heart is now regarded as a relatively late consequence of low arterial pressure rather than its cause, it seems well worth while to pursue further the efforts to restore blood volume and thereby maintain adequate return of blood to the heart and a safe arterial pressure in shock. This immediately helpful feature may be undertaken quite apart from the means to combat the ultimate etiologic factors, such as are represented by the postulated and much discussed tissue poisons, acidosis, etc., which are supposed to deteriorate the normal exchange of fluid through the vessels, or occasion stagnation of blood in certain areas. Erlanger and Gasser⁷ of Washington University in St. Louis have convinced themselves, in a series of animal experiments on traumatic shock, that the viscosity of strong gum solutions may be quite harmful, but that when hypertonic gum and hypertonic glucose are given simultaneously and slowly so as to avoid altogether the period during which the high viscosity of the gum is hampering the circulation, a maximum saving of life can be effected. They argue that such beneficial results as they saw are presumably due to the internal transfusion effected by the hypertonic solutions, to the maintenance of the increased blood volume through the colloidal and possibly other properties of the gum acacia, to the action of the hypertonic solution on the heart and blood vessels, and to the specific action of glucose on nutrition in general and on that of the heart muscle in particular. They suggest, further, that blood transfusion is not essential to recovery even from the severest acute hemorrhage, if only the blood bulk can be restored in other ways. The apparent innocuousness of gum-glucose solutions given slowly has already justified a few trials on man⁸ which encourage further tests of the method. With the principles and certain limitations of the procedure well recognized through preliminary animal experimentation, the surgeon will be justified, we believe, in giving them further trial in the emergencies of shock that so often fail to yield to current modes of treatment.

HIGH PROTEIN DIETS AND NEPHRITIS

The science of pathology is still far from formulating an entirely satisfactory hypothesis for the genesis of all forms of nephritis. It is known, of course, that incident to the attempts of the kidney to eliminate certain substances like the salts of mercury or uranium or several other metals, a tubular nephritis of varying intensity may arise; and the acute injury may subsequently become chronic in its manifestations. There is considerable justification for the belief that the reaction of the secreted urine, which in turn is dependent on the nature of the food intake, is not without

influence on the behavior of the kidney cells under secretory stress. Usually, however, the etiology of nephritic changes is sought in some foreign factor, such as the inorganic possibilities just cited, or nephrotoxins or nephrollysins assumed to arise within the organism itself.

Although the alleged "strain" of eliminating a large quantity of those substances, namely, the products of protein catabolism in the body which the kidney is normally intended to excrete, has been pointed to from time to time as a possible cause of kidney damage, there has been little convincing evidence for such an outcome. Urea, which represents the great bulk of the nitrogenous waste, is evidently excreted with great ease. There are numerous recorded instances of large increments in urea output without any signs of kidney defect or detriment; but experiments to determine the functional efficiency of the kidney have usually been of comparatively short duration. The clinical forms of nephritis are frequently slow in making their appearance. Newburgh¹ has therefore attempted, in the department of internal medicine at the University of Michigan, to ascertain whether nephritis will be produced when the kidneys have been eliminating an unusually large amount of nitrogenous material over a considerable period of time. He argues that just as the kidney secretes ordinary medicinal doses of mercury without harm, but is injured when the quantity offered for elimination in a given time is augmented greatly, as it is in acute poisoning, so the renal cells may react unfavorably if the quantity of some or all of the nitrogenous substances secreted is increased and kept at the higher level for some time. In feeding experiments on rabbits, renal injury was quickly and constantly noted in animals that ate several egg whites daily. Prolonged egg white feeding caused acute and subacute nephritis. When the nitrogenous metabolism was increased by means of casein, rabbits suffered no demonstrable renal injury from eating 15 gm. of casein daily; but when the daily intake of casein was 30 gm., and the nitrogen metabolism was about three times normal, a well marked deleterious effect on the kidney was produced. Rabbits that lived for months on soy beans, which are rich in vegetable proteins, regularly acquired chronic nephritis and frequently died of it. The nitrogen metabolism from this diet was about twice the normal.

We may accept these observations, which are likely to be widely quoted by the advocates of a low protein diet or at least of greater economy in the use of protein, without admitting their wider significance in the etiology of human nephritis. The vegetarians will find little solace in the fact that sources of plant proteins were involved as well as the tabued animal products. Urea per se is not charged with the harm done. It must be remembered that the diets used by Newburgh

were potentially acid in character, and certain to produce an acid urine in a species adjusted and accustomed to secrete an alkaline fluid under a free choice of food. Until such experiments are successfully duplicated under conditions in which the normal reaction of the renal secretion is not tremendously altered and the accessory factors in the diet are known to be adequate, the incrimination of the high protein diets in connection with nephritis must be considered with judicial reserve.

THE ERADICATION OF TUBERCULOSIS

In the control of a disease like tuberculosis, which permeates all strata of society and which is obviously of an infective nature, there are clearly two factors concerned. It is, of course, essential that the disease should be scientifically studied from all aspects; but it is also necessary that the scientific knowledge that has been gained shall be transmitted in comprehensible form to the masses. There is no disease that has been more systematically and more intelligently combated than tuberculosis, and yet we have no more than scratched the surface. The disease continues to be one of the greatest scourges to which civilized man is subjected. Indeed, it is, as Krause¹ remarks, "a price we pay for our civilization."

In a recent address on the subject, Krause discusses the question of a progressive program for combating this disease. Incidentally, he points out, what had already become apparent, that the fight against tuberculosis will really be a fight against all diseases of an infectious nature; for the same principles underlie the prevention and cure of all parasitic disease. It is interesting to note that the keynote of this address by a scientific student of tuberculosis is not the necessity for further scientific investigation, though this is not denied, but the necessity for the wider application and diffusion of facts already long known, and for a much greater attention to the social aspects of the disease. Of what profit is our scientific knowledge of the etiology of tuberculosis if we fail to apply its obvious lessons? As Krause properly points out, we fail to control the most outstanding and obvious etiologic factors in the spread of tuberculosis. The statute books of our states are replete with antisputting laws, and yet our highways are spattered with expectoration. The regulations of boards of health on the subject of clean milk are voluminous, and yet clean milk is frequently unobtainable by the masses.

These, however, are not the only obvious factors that are neglected. As physicians we have known for generations that tuberculosis is undoubtedly associated with unsatisfactory social conditions. Poverty, insufficient or improper food, alcoholism and insanitary housing all predispose to the activity of tuberculosis infection. It may be said that the adjustment of such

conditions does not lie within the realm of the physician. The reforms that are necessary to change them must occur partly as the result of political action, and partly as the result of education. While there are some who hope to change these unfortunate conditions by revolutionary methods, there seems to be little reason to anticipate that much will be accomplished in this way.

SOME FEATURES OF ASCARIASIS

Ascariasis, or infestation with the eelworm, *Ascaris lumbricoides*, is one of the most common invasions of man by animal parasites. Although it is usually more frequent in childhood, it may occur at any age in the human subject. *Ascaris* is one of the parasites that have generally been asserted to develop in man by the direct method. No intermediate host is required. The swallowed eggs begin their transformation into the lumbricoid worm directly in the alimentary tract. A comparable roundworm is of very frequent occurrence in the intestine of the pig.

Stewart¹ has attempted without success to infect pigs by feeding *Ascaris* eggs to them. Rats and mice, on the other hand, were readily infested by this procedure. In the course of these studies he observed that the larvae find their way into the tissues and particularly into the liver and lungs of the host. The larvae then find their way back to the intestinal tract after migration through the pulmonary tissue, and may ultimately pass out of the alimentary canal without further development. This migration of the larvae of *Ascaris* has also been verified in experiments conducted by Yoshida² at the Osaka Medical Academy in Japan. These observations of the larval parasites in rats and mice, taken in connection with the apparent resistance of the pig to direct infestation with eggs, have raised the question as to whether the rodents act as intermediate hosts, the young worms being passed on to human beings (and to pigs) through the contamination of food and water by the saliva or feces of rats and mice that had themselves become infested by swallowing the eggs of the parasite.

More recent investigations by Ransom and Foster³ at the Bureau of Animal Industry in Washington indicate that it is not necessary to assume an intermediate host in the case of *Ascaris* infestation in man. The real explanation, they remark, of the behavior of *Ascaris* larvae in rats and mice is that the worms are merely going through the same course as they do in their usual hosts, man and pig. The rats and mice are, however, unsuitable hosts; hence the larvae are unable to complete their development to maturity in

them; whereas in human beings the parasitic larvae, after migration through the lungs and return to the alimentary canal, can continue their growth to an adult stage.

The "wanderings" of eelworms in man have been recognized for a long time, and such cases present a dangerous aspect of ascariasis.⁴ That the erratic ascarids may produce lung symptoms in man is more than likely. Ransom and Foster therefore properly remind us, in commenting on Stewart's interesting discovery of the migration of *Ascaris* larvae through the lungs, that this new aspect of the pathology of eelworm infestation is likely to lead to a better understanding of certain obscure diseases of the pulmonary organs. Other dangers from the migrations, whereby perforations of ulcers, liver complications, or other abdominal symptoms have arisen, are recorded in medical literature. Eelworms ought, therefore, to be treated as something more than a "passing curiosity."

Current Comment

MEDICAL VETERANS OF THE WORLD WAR

Our profession responded unselfishly to the call of our country during the world war. The demand for medical men was tremendous, but it was met. Including the 35,000 of the regular services, and the more than 25,000 on the selective service boards, over 60,000 physicians enlisted to support the ideals that the United States has endeavored to maintain. Although our entrance into the conflict was followed by a speedy victory, although our sickness and mortality rates were matters of pride and signalized a great achievement by the medical profession, it is no secret that these happy results were accomplished, in many instances, by great personal sacrifice and by altruistic devotion. In other words, unsatisfactory conditions in many instances were tolerated "for the good of the service"—to win the war—and the physician could only promise himself that should future occasion arise, certain things must be corrected. At the Annual Session of the American Medical Association, immediately following the termination of the war, a group of physicians who had been in the military service, having in mind their experiences, effected the organization known as the Medical Veterans of the World War, and invited into its membership not only those connected with the government services but also those who had served on the selective service boards. Dr. Vaughan,⁵ whose letter was published last week, and Surgeon-General Ireland,⁶ who discusses the subject in this issue of THE JOURNAL, believe that this organization is entitled to support. It should make possible a united effort by which the greatest good may be accomplished. Many things can be done that otherwise would remain undone. It offers a medium for the presentation of constructive criticism.

Finally, through this organization particularly may be preserved, by occasional gatherings, the sympathetic comradeship of men whose ideals today are as high as they were during the war.

BOTULISM FROM CANNED RIPE OLIVES

In recent editorials¹ THE JOURNAL has summarized our knowledge of botulism, especially with relation to extensive investigations made under the auspices of the National Canners Association and in the laboratories of the Leland Stanford University. Because of the violence of the symptoms and the rapidly fatal issue of poisoning with the toxins of *Bacillus botulinus*, the subject has interest beyond the extent of its relative importance in mortality statistics. The recently reported deaths following the eating of ripe olives in Detroit and in Canton, Ohio, were especially significant, because first reports seemed to indicate that the use of the ordinary precautions would not protect the user against such contingencies. There is now available more detailed report of these cases. We are informed² of some significant factors that have a practical bearing: First, various members of the party at the banquet in Canton, Ohio, in describing the olives used such expressions as, "Smelled like limberger," "bit the tongue," "soft," "not fit to eat," "stuck to the tongue," etc. Second, it was found that some of the olives had been washed previous to serving and that one person who ate two of these olives recovered. These factors would seem to lend strength to the contention of Weinzirl that the observance of ordinary precautions in eating, such as cleanliness, and the rejection of all food of which there is a suspicion of spoiling, will, in many cases at least, protect the user.

PROHIBITION AND THE DEATH RATE

The large number of deaths recently caused by the drinking of wood alcohol should not lead the public to overlook the important drop in the death rate from certain causes that has followed the legal prohibition of alcoholic beverages. Recent statistics³ show that for July, August and September, 1919, the number of deaths in Boston from alcoholism amounted to only 7, as compared with 31, 46, 38 and 34 for the corresponding period of the four preceding years. Similarly, accidents diminished from 152 in 1915, 176 in 1916, 197 in 1917 and 151 in 1918 to 112 for the corresponding three months of 1919. Suicides also diminished to a very marked degree. On the other hand, homicides showed no material decrease, a fact that has been noticed in other cities. It seems probable, however, that certain unusual factors are at work to increase the number of murders. As is usual after a great war, familiarity with means of violence and readiness to resort to such means are circumstances that must be reckoned with during the slow return to law and order. The diminution in the deaths from

alcoholism, accident and suicide that has occurred in Boston has been observed in many other large American cities, and the saving of life from these causes probably far exceeds the increased number of deaths from wood alcohol poisoning.

THE PRODUCTION OF PRESSURE SYMPTOMS BY NORMAL RIBS

The rôle of cervical ribs in the production of pressure symptoms has been understood for some time, though it is only since the introduction of the roentgen ray as an aid to diagnosis that the frequency of such lesions has been appreciated. Stopford and Telford have recently pointed out that not only cervical ribs but also perfectly normal first ribs may give rise to a similar syndrome. There are peculiarities about the production of symptoms in connection with rib pressure that may with propriety be recalled at this time. It is to be noted that women are more likely to develop such symptoms than men, although they are no more prone to the development of cervical ribs. It is further to be noted that although the rib abnormality is frequently present from birth, the symptoms may not appear until puberty or even later. In some instances trauma plays a definite part in producing the symptoms, particularly injuries that involve the trapezius muscle and interfere with its function as a support to the shoulder girdle. In other cases the symptoms appear spontaneously and without obvious reason, though in these patients also it may be that a lack of tone in the trapezius muscle is responsible. The pressure, no matter whether it is exerted by a cervical rib or by a normal first rib, is almost always on the lower trunk of the brachial plexus. The symptoms are more or less variable, depending on whether the motor, sensory or sympathetic fibers are mainly involved. Patients are likely to complain of neuralgic pain along the ulnar side of the forearm. They may develop partial paralysis of the intrinsic muscles of the hand and of the flexors and extensors of the wrist. Atrophy may occur, and often trophic and vasomotor phenomena are present. Pallor or cyanosis of the fingers, hypothermia, and even trophic ulcers in the distribution of the ulnar nerve have been noted. Objective sensory disturbances in which the protopathic sensibility is more pronouncedly affected than the epicritic sense may result, and in rare cases decidedly elective sensory paralyses are present. Attention is called at this time to those in whom the symptoms are due to a normal first rib, because these cases are not particularly uncommon. Stopford and Telford saw ten such cases in less than two years. In the diagnosis the roentgen ray is of no value, and in the past such cases have doubtless been wrongly diagnosed and wrongly treated because roentgenograms failed to show the cervical rib, and because the clinician did not recognize that a normal first rib could cause pressure and lead to the same syndrome.

Association News

THE NEW ORLEANS SESSION

Headquarters for the Registration Bureau and the Exhibits

The Josephine Hutchinson Memorial Building, the home of the Tulane University School of Medicine, will house the Registration Bureau, the Information Bureau, the Association branch postoffice, and the Scientific and Commercial exhibits. It will also provide meeting places for three of the sections. Thus, the coming annual session will center at Tulane. The Hutchinson Memorial Building is near the business center of the city on Canal Street, between Villere and Robertson. This convenient location, the attractions of the exhibits, and the assured hospitality of the Louisiana profession extended through the Tulane Medical School assure a hearty welcome to those who attend the annual session at New Orleans, April 26 to 30, 1920.

Hotel Headquarters

The following hotels have been designated as the general and the various section headquarters for the New Orleans Session:

PRACTICE OF MEDICINE: St. Charles.
SURGERY, GENERAL AND ABDOMINAL: Grunewald.
OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY: Grunewald.
OPHTHALMOLOGY: Monteleone.

The Josephine Hutchinson Memorial Building, Headquarters for the New Orleans Session.

LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY: Monteleone.
DISEASES OF CHILDREN: St. Charles.
PHARMACOLOGY AND THERAPEUTICS: Planters.
PATHOLOGY AND PHYSIOLOGY: Planters.
STOMATOLOGY: Lafayette.
NERVOUS AND MENTAL DISEASES: Lafayette.
DERMATOLOGY: De Soto.
PREVENTIVE MEDICINE AND PUBLIC HEALTH: De Soto.
UROLOGY: St. Charles.
ORTHOPEDIC SURGERY: Grunewald.
GASTRO-ENTEROLOGY AND PROCTOLOGY: Lafayette.
GENERAL HEADQUARTERS: Grunewald.

To New Orleans by Boat

Inquiries received from various parts of the country indicate that a number of physicians would like to make the trip to New Orleans by boat. These prompt the suggestion that physicians conveniently near to the Atlantic Sea Board and Gulf ports, as well as those at different points along the Mississippi and Ohio rivers, might arrange boat parties which should provide a pleasant and restful journey. It has been suggested further that if boats were chartered to go to New Orleans from different points and were docked there, these "house boat parties" would provide cool and delightful quarters for those who prefer to stay on the boats during the session.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Hospital Items.—The trustees of Spark's Memorial Hospital, Fort Smith, have purchased a building in which they propose to install a laboratory costing \$5,000.—A new sanatorium has been built and equipped at Arkadelphia, by Drs. Charles Wallis and J. Sheppard Moore.

New Officers.—The First Councilor District Medical Society at its meeting in Jonesboro, December 10, elected Dr. Hiram L. Throgmorton, Pocahontas, president; Dr. Charles M. Litterloh, Jonesboro, vice president, and Dr. Thad Cothorn, Jonesboro, secretary-treasurer.—Jefferson County Medical Society at its annual meeting, December 2, elected Dr. Mark A. Shelton, Wabbaseka, president; Dr. James F. Crump, Pine Bluff, vice president, and Dr. Joseph F. Gill, Pine Bluff, secretary-treasurer.—Drew County Medical Society at its annual meeting, December 2, elected Dr. Mardelle Y. Pope, president; Dr. Edward R. Cotham, vice president, and Dr. A. S. J. Collins, secretary-treasurer, all of Monticello.

ILLINOIS

Low Death Rate.—The death rate of Chicago for 1919 was 12.76 per thousand, the lowest in the history of the city.

Hospital Item.—Announcement is made that a United States Public Health Hospital is to be established at Great Lakes, the barracks of naval units No. 19 and No. 20 being employed for this purpose, after remodeling.

Fined for Insufficient Heat.—A number of landlords who have failed to provide sufficient heat for their tenants have been fined from \$50 to \$200 each. On hearing the evidence in one case, the court assessed the maximum penalty and ordered the defendant committed until the fine had been paid. So far as is known, this is the first fine imposed for an offense of this kind in the history of the Chicago Department of Health. The health commissioner caused the arrest of these persons on complaints of the tenants and of physicians who had patients resident in the buildings concerned.

Chicago

Society of Medical History to Hear Drs. Wood and Garrison.—The Society of Medical History of Chicago will meet January 17, at 8 p. m. at the City Club, to hear addresses by Col. Casey A. Wood, on "Walter Bailey, the First Writer of an Ophthalmic Treatise in English," and by Lieut.-Col. Fielding H. Garrison, on "Medical Men and Music," and "Remarks on the Medical History of the War." Those desiring to attend should notify the secretary, Dr. Stanton A. Friedberg.

INDIANA

Personal.—Dr. John A. Scudder, Edwardsport, is ill with septicemia in the Good Samaritan Hospital, Vincennes.

Banquet to Health Department Employees.—Dr. John N. Hurty, secretary of the state board of health, and Dr. William F. King, assistant secretary, gave their annual Christmas dinner to employees of the department, December 24.

Open Air School.—A new open air school has been opened by the Indiana State Sanatorium, with a capacity for about forty children. It is planned to introduce vocational work in the school, both for its therapeutic value and utility in later life. The general course of the state will be followed, interspersed with simple breath and muscular exercises and regulated rest periods.

Will Appeal Smith Case.—The state board of medical registration and examination has employed W. A. Cullop, Vincennes, as its attorney to carry to the supreme court its case against Dr. George F. Smith, Bicknell, whose license to practice medicine was revoked in February last year. A circuit court judge in Knox County decided against the board and ordered the license restored.

Verdicts For and Against Physicians.—In the case of Robert Frederick Volland against Dr. David J. Marshall,

Columbus, in which \$10,000 damages was claimed on account of severe burns alleged to have been the result of hot water overflowing on the complainant, the jury, December 19, returned a verdict in favor of Dr. Marshall.—In the case of Raymond Uland, Sullivan, against Drs. Edward T. Edwards and Vance A. Funk, both of Vincennes, in which malpractice was alleged, and damages of \$15,000 were asked, a jury, December 18, decided in favor of the plaintiff, awarding him \$2,000.

IOWA

New Officers.—Dubuque County Medical Society, at its annual meeting, December 9, elected the following officers: Dr. Charles Palen, president; Drs. Alanson M. Pond, Dubuque, and Richard C. Sherman, Farley, vice presidents; Dr. James E. Calhoun, Dubuque, secretary, and Dr. Godfrey C. Fritschel, Dubuque, treasurer.

Warning.—A report has been received that a tall, smooth-shaven man of fine appearance, passing under the name of J. T. McMillan, with graying hair, parted near the center, and brushed toward the sides in a wave, and weighing from 180 to 190 pounds, has been making contracts for the Lee Supply Company of Detroit, which is said to be out of business. This man is wanted by the police and information regarding him should be sent to the chief of police, Fort Madison.

KENTUCKY

Full-Time Health Department Voted Down.—The Harrison County fiscal court, at a special session, December 13, voted down the proposition for a full-time health department for the county by a vote of four to two. The movement was endorsed by the Harrison County Medical Society, Pomona Grange, Harrison County local Red Cross chapter, women's clubs and other organizations.

Health Work.—Dr. Platt W. Covington of the International Health Board has been loaned to Kentucky to assume the directorship of county health work. The state board of health is now in position to give \$5,000 annually to the first five counties making like appropriations.—The fiscal court of Daviess County appropriated \$5,000, December 11, toward a clinic to be established by the Rockefeller Foundation.

Personal.—The board of control of penal and charitable institutions has reappointed Dr. Frank L. Peddicord, Lakeland, superintendent of Lakeland Hospital for a term of four years, from May, 1919.—Dr. Clifford E. Harkey has succeeded Dr. Elbert W. Jackson as physician of Paducah.—Dr. Harry H. Lewis, Louisville, who has been on trial for murder of his wife, is said to have been declared of unsound mind by the jury.

New Officers.—At the annual meeting of the Clark County Medical Society at Winchester, December 31, Dr. Howard Lyon was elected president; Dr. Edward P. Guerrant, vice president, and Dr. George F. Doyle, secretary and treasurer, all of Winchester.—Daviess County Medical Association, at its annual meeting held in Owensboro, December 16, elected Dr. John C. Hoover, Owensboro, president; Dr. Cicero M. Rice, Sutherland, vice president, and reelected Dr. John J. Rodman, Owensboro, secretary-treasurer.

LOUISIANA

Another Plague Victim.—John Rich, a negro patient in the Charity Hospital, New Orleans, was found to have bubonic plague, and was removed to the Isolation Hospital, December 29.

Maternity Clinic to Be Opened.—A maternity clinic was opened at the Kingsley House, New Orleans, December 23, under the direction of Dr. Phillips J. Carter and Miss Grete Judice, nurse of the child welfare staff. The clinic is one of five which will be operated under the auspices of the Kingsley House and the Child Welfare Association.

Parish Society Election.—At the annual meeting of the Orleans Parish Society, December 13, the following officers were elected: president, Dr. Hector E. Bernadas; vice presidents, Drs. Hamilton P. Jones, Jerome E. Landry and Joseph M. Hountha; secretary, Dr. Edward P. A. Ficklen, and treasurer, Dr. Foster M. Johns, all of New Orleans.

MARYLAND

Appointment to Health Department.—Dr. William T. Howard, Jr., former assistant commissioner of health, has returned to the Baltimore City Health Department as a con-

sultant and expert in statistics. Dr. Howard will continue his duties as teacher in the Johns Hopkins School of Hygiene.

Mortgage Paid Off.—The committee to which was entrusted the securing of funds to pay off the mortgage on the building of the Medical and Chirurgical Faculty of Maryland Library, Baltimore, and of which Dr. W. Edward Magruder, Baltimore, was secretary, completed its work on the day the death of Sir William Osler, who made the first contribution of \$1,000 to the fund, was reported in Baltimore.

To Direct School Health Work.—With the idea of making the medical inspections of the schools of Baltimore more effective, Health Commissioner C. Hampson Jones has placed the work under the direct supervision of Dr. H. Warren Buckler, who now heads one of the divisions of the health department. For this work he will have the assistance of the twenty-eight health wardens. The new division will include the sixteen school nurses and the seven physicians who heretofore have reported directly to the commissioner of health. With the health wardens at his call, Dr. Buckler will have a large force of physicians available for examining schoolchildren, thus keeping the schools free from infectious and contagious diseases.

Services in Honor of Dr. Osler.—A notable gathering of members of the medical profession and other friends of the late Sir William Osler attended services in his honor at 3:15 o'clock on January 1, in Old St. Paul's Church, Baltimore. The time was set on receipt by Dr. Henry Barton Jacobs of a cablegram from Lady Osler, stating that the funeral services in England for the famous physician would be held at that hour. The ceremony at St. Paul's was most impressive. The trustees, faculty and student body of the Johns Hopkins University were represented, as well as the nurses of the training school and officials of Johns Hopkins Hospital. The Medical and Chirurgical Faculty of Maryland and the Baltimore City Medical Society were represented by leading members of the medical profession.

Tribute to Dr. Hurd.—The *Bulletin of the Johns Hopkins Hospital* for December contains a record of the work and writings of Dr. Henry Mills Hurd, Baltimore, who was the first superintendent of the hospital. Portraits of Dr. Hurd are shown from the age of 6 to the present time. Dr. Thomas S. Cullen, Baltimore, is the author of the article on Dr. Hurd and has arranged the record of his hospital reports year by year, so that an admirable history of the hospital is presented in small space and biographical data is placed in the record of each year. Dr. Cullen draws special attention to the tremendous amount that Dr. Hurd has accomplished and of how largely he has been responsible for the phenomenal success of the hospital. He also speaks of the splendid tribute to Dr. Hurd in the "Henry M. Hurd Library" of the hospital, plans for which are under way and the funds for which were the gift of the late George K. McGaw.

MASSACHUSETTS

Influenza Research.—Dean David L. Edsall of Harvard Medical school announces a gift of \$50,000, the greater portion of which will be used by Dr. Milton J. Rosenau, professor of preventive medicine and hygiene, and his assistants to carry on exhaustive studies and research, to discover some means to prevent future outbreaks of influenza epidemics.

Personal.—Dr. Richard P. Strong, Boston, has been appointed chief medical director of the League of Red Cross Societies of the Nations of the World, with headquarters at Geneva.—Dr. Charles E. Prior, Malden, has been appointed a member of the state board of registration in medicine, succeeding Dr. Charles H. Cook, Natick, deceased.—Dr. Lowell F. Wentworth, Boston, has been appointed assistant commissioner in the department of mental diseases of the state department of health.—Dr. Hamlin P. Bennett, Lynn, was attacked by automobile thieves at a garage recently, and beaten into insensibility.

MICHIGAN

Personal.—Dr. Alvin L. Bailey, Chesaning, was struck by an automobile at Saginaw, recently, and suffered severe injuries.—Dr. Edwin M. Chauncey, Albion, has been appointed assistant in the internal medicine department of the University of Michigan.

Bulletin Michigan Department of Health.—The December issue of this bulletin is devoted entirely to the subject of cancer. It is discussed in such a way that the layman can understand what is said. This bulletin was prepared with

the cooperation of the American Society for the Control of Cancer.

Hospital Items.—Work is already under way on the new University Hospital, Ann Arbor.—The Will Curtis residence, Reed City, has been purchased and will be occupied as a hospital in place of the one recently destroyed by fire.—The Lange Hospital, Lansing, has been temporarily leased to the Sisters of Mercy of Jackson and will be operated by them until they can locate a proper site and erect a new building. It will be opened for service to the public, January 15. It is the purpose of the Sisters of Mercy to locate here, and through the operation of the Lange Hospital they hope to determine the needs of the city before building the new hospital.

MINNESOTA

Osler Memorial Meeting.—A meeting of the staff of the Mayo Clinic, Rochester, was called, December 31, in honor of the late Sir William Osler.

Personal.—Dr. Harry A. Britton, acting superintendent of city hospitals, Minneapolis, and Dr. Harry M. Guilford, city health commissioner of Minneapolis, have resigned.

Red River Valley Physicians Meet.—At the annual meeting of the Red River Valley Medical Society held in Crookston, the last week in December, Dr. O. Edward Bratrud, Warren, was elected president; Dr. Ralph L. Kirsch, Crookston, vice president, and Dr. Hallward M. Blegen, Warren, secretary-treasurer.

NEBRASKA

Personal.—Dr. Philip H. Bartholomew, Blue Hill, has succeeded Major Leader as head of the venereal disease work in Nebraska.

Society Election.—The Omaha and Douglas County Medical Society held its annual meeting and banquet, December 22, and elected the following officers: president, Dr. Paul H. Ellis; vice president, Dr. Arthur D. Dunn, and secretary-treasurer, Dr. Roy A. Dodge, all of Omaha.

Alumni Elect Officers.—At the ninth annual alumni meeting of the University of Nebraska, College of Medicine, held in Omaha, November 20, the following officers were elected: president, Dr. Charles R. Kennedy, Omaha; vice presidents, Drs. Jacob E. Meisenbach, Staplehurst, and John C. Davis, Jr., Omaha, and secretary-treasurer, Dr. William N. Anderson, Omaha.

NEW YORK

Erie County Society Elects New Officers.—At the ninety-eighth annual meeting of the Erie County Medical Society, December 16, the following officers were elected: president, Dr. Earl P. Lothrop; vice presidents, Drs. Arthur G. Bennett and DeWitt H. Sherman; secretary, Dr. Franklin C. Gram (reelected for the twenty-seventh consecutive term), and treasurer, Dr. Albert T. Lytle, all of Buffalo.

Hospital Items.—Bethesda Hospital, Hornell, has been raising funds for a new building.—It is reported that the buildings of the U. S. General Hospital No. 8, Otisville, are to be destroyed, as the New York Health Department does not allow the removal of buildings that have been occupied by tuberculosis patients for use in other places, and since the buildings for this hospital were erected on the grounds owned by the New York City Sanitarium, the rule is said to be effective in this case.

State Death Rate Higher.—The latest vital statistics report of the New York State Health Department shows that the general death rate for the state increased slightly in November over that of the preceding month, though it was still 17 per cent. below the average death rate for that month during the past five years. The birth rate for November was 20.4 per thousand population, which is much below the average for the years 1913-1917. The infant mortality rate for November was 66, which is 19 points below the average for that month. The number of deaths from diphtheria increased during the month of November, being 187 as compared with a five years' average of 142 for the same month.

Preschool and Other Clinics Established.—The Visiting Nurses' Association of Watertown, which has been conducting a child welfare clinic, has recently opened a preschool clinic, which is under the direction of Dr. Horace C. Montgomery, Watertown, and Miss Carey.—The board of health of the city of Elmira has authorized the establishment of a general clinic to include child welfare work and measures against tuberculosis and venereal disease.—At New

Rochelle, a committee has been appointed to interest the people of the community in a health center.—At Gloversville, a committee has been named by the board of health for the purpose of securing suitable quarters for a health center.

New York City

Smallpox on Ship.—On the arrival of the steamer *Duca Degli Abruzzi* from Genoa and Naples, January 3, two cases of smallpox were found on board. The patients were removed to Swinburne Island, and the 1,300 steerage passengers will be held on Hoffmann Island three weeks for observation.

Low Death Rate.—Health Commissioner Royal S. Copeland announced, January 3, that the death rate for greater New York was lower than any year since the department has been organized. For 1919, the mortality rate was 12.30 per thousand; 1918, 16.71 per thousand, and for the five preceding five-year periods, 13.94 per thousand.

Mary Putnam Jacobi Fellowship.—The Women's Medical Association of New York City offers this Fellowship of \$800, available for postgraduate study. It is open to any woman physician for work in any of the medical sciences. Applications for the year 1920-1921 must be in the hands of the committee on award by April 1, 1920. For information address Dr. Rose Cohen, secretary, 151 West Seventy-Eighth Street, New York City.

Organizations Warn Against Wood Alcohol.—A record of fifty-one deaths and at least one hundred cases of blindness due to wood alcohol during the first twenty days of December, has aroused to action the National Committee for the Prevention of Blindness, the New York Academy of Medicine, the department of health and Chief Medical Examiner Charles Norris. These agencies, after a conference, issued a warning to the public of the danger of drinking anything in the saloons that passed for whisky. Dr. Ward A. Holden has been designated by the committee on public health and hygiene of the New York Academy of Medicine to make an exhaustive study of wood alcohol in relation to blindness.

Personal.—Dr. Charles F. Hunt has been elected surgeon of the Defendarm Association.—Theodore C. Lyster, Col., M. C., U. S. Army, who has been with the yellow fever commission in Ecuador, Colombia, and Southern Mexico, since March, 1918, returned to New York on the *Esperanza*, December 21.—Dr. Jacques Loeb of the Rockefeller Institute for Medical Research has been elected an honorary member of the Royal Institution of Great Britain and Ireland.—Wickliffe Rose, chief director of the International Health Board of the Rockefeller Foundation, and Dr. Richard M. Pearce, Philadelphia, director of the division of medical education of the board, sailed for Europe, December 11, to secure information about public health administration and methods of medical education in England and on the Continent.

OKLAHOMA

Personal.—Dr. George W. Goss, Pawhuska, has been appointed superintendent of health for Osage County.

New Officers.—Muskogee County Medical Society, at its annual meeting, elected the following officers: president, Dr. Pleasant P. Nesbitt; vice president, Dr. Joseph H. Sanford, and secretary, Dr. Joseph G. Noble, all of Muskogee.—Woodward County Medical Society elected the following officers: president, Dr. Ralph A. Workman, Woodward; vice president, Dr. Paul G. Eilers, Quinlan, and secretary, Dr. Charles W. Tedrowe, Woodward.—Kay County Medical Society met at Blackwell, December 11, and elected Dr. James C. Hawkins, Blackwell, president; Dr. Ralph P. Mavity, Braman, vice president, and Dr. Isaac D. Walker, secretary-treasurer.—At the annual meeting of the Tulsa County Medical Society, Dr. Gregory A. Wall was elected president; Dr. Fred S. Clinton, vice president, and Dr. Albert W. Pigford, secretary-treasurer, all of Tulsa.

PENNSYLVANIA

Mellon Lectures.—The fifth Mellon lecture of the Society for Biological Research of the University of Pittsburgh was delivered by Major-Gen. William C. Gorgas, M. C., U. S. Army (retired), January 8, on "Yellow Fever," illustrating the application of modern sanitation and preventive medicine in the control of epidemic diseases.

Physicians Held Under Prohibition Law.—Four physicians of Pittsburgh and one druggist were arrested, December 27,

and are held under \$1,500 bonds each on a charge of violation of the war-time prohibition law. The physicians were charged with prescribing whisky to a special agent of the department of justice, and the druggist was charged with having sold a quart of whisky "for beverage purposes."

Public Health Activities.—To promote the public health and social welfare of the people of Lehigh County, a public health and welfare society has recently been organized in Allentown, of which Dr. Charles D. Schaeffer is president and Dr. J. Treichler Butz is vice president.—The new county health committee, under the guidance of Dr. Howard C. Frontz, Huntingdon, county medical director, have outlined a health program for the county which will be conducted on the broadest lines and include a tuberculosis committee to be affiliated with the Pennsylvania Society for the Prevention of Tuberculosis.

Personal.—Dr. Walter W. Seibert, Easton, has been appointed a trustee of the State Hospital, Rittersville.—Dr. Chester G. Crist, Gettysburg, has been elected coroner of Adams County.—Dr. Thomas M. Baird, Tunkhannock, recently discharged from service, has been commissioned lieutenant-colonel, M. R. C., U. S. Army.—Dr. Raleigh R. Huggins, Pittsburgh, has been appointed dean of the faculty of the School of Medicine of the University of Pittsburgh, succeeding Dr. Thomas S. Arbuthnot, resigned.—Dr. Henry C. McKinley, Meyersdale, has been elected secretary of the Somerset County Medical Society for the thirty-first consecutive time, having served for thirty years, or since the organization of the society.—Dr. William J. Crookston, Pittsburgh, has been commissioned lieutenant-colonel, Medical Corps, N. G., Pa., and assigned to duty with the first division.—Dr. Dewitt B. Nettleton, Pittsburgh, has been commissioned major, M. C., N. G., Pa., and assigned to duty with the First Field Artillery.—Dr. Constantine P. Faller, Carlisle, has been commissioned major, M. C., N. G., Pa., and assigned to duty with the Eighth Infantry.

The Wood Alcohol Question.—The commissioner of health of Pennsylvania has issued the following advertisement:

"TO MANUFACTURERS, DISTRIBUTORS AND DEALERS"

Owing to the unusual conditions arising in neighboring states from the sale and distribution of mixtures containing wood alcohol which has resulted in a large number of deaths, the Pennsylvania State Department of Health in conjunction with the Pennsylvania Food Commissioner and the Pennsylvania Board of Pharmacy and the Attorney General's Department hereby serves notice upon manufacturers, distributors and dealers that an embargo will be placed upon all non-official preparations containing alcohol unless the manufacturer, dealer or distributor of such preparations satisfy by affidavit the State Department of Health that the preparations do not contain wood alcohol. The affidavits must be filed with the State Department of Health on or before January 8th, 1920.

EDWARD MARTIN, Commissioner of Health.

By the act of July 17, 1919, the putting of wood alcohol in medicines, toilet preparations, etc., is punishable by a fine of \$500, and Thomas S. Blair, Harrisburg, chief of the bureau of drug control, has nine inspectors going over the state to examine into the enforcement of the law.

Philadelphia

Testimonial Dinner to Dr. Krusen.—A testimonial dinner to Dr. Wilmer Krusen, former director of public health and charities, was given by the physicians of Philadelphia at the Bellevue-Stratford, December 30. Dr. Hobart A. Hare was the toastmaster.

Pathologic Laboratory Dedicated.—At the dedication of the new pathologic laboratory of the Philadelphia General Hospital, the principal address was delivered by Dr. William H. Welch of Johns Hopkins University, who spoke of the important part played by morbid anatomy in the advancement of medicine. Addresses were also made by Dr. Arthur D. Bevan, Chicago, and Louis B. Wilson, Rochester, Minn.

Assistant Health Director Appointed.—Col. C. Lincoln Furbush, the newly elected director of public health and charities, has appointed as his assistant director, Dr. Norman H. Taylor of Chestnut Hill. Dr. Taylor after his graduation from Harvard Medical School was chief resident physician at the Pennsylvania Hospital before the war; he became first lieutenant in the Medical Corps of the Army and attended vacation courses at the Sorbonne, Paris.

Navy Hospital Abandoned.—After continuous use since the Civil War days, the United States Naval Hospital, at Twenty-Fourth and Gray's Ferry Road, has been ordered abandoned by the United States Navy Department. The

250 patients in the institution at the present time, will gradually be removed to the new naval hospital at the Philadelphia Navy Yard which has accommodations for 1,000 men. Besides the old hospital of Civil War days, three fine modern structures, which were erected in 1918, will be left vacant. It is thought that they may be made into an extension of the United States Naval Home on the grounds of which they are located, but no orders have been received to that effect.

Personal.—Dr. Ellen C. Potter, having been appointed a special lecturer in the health department of the Bryn Mawr College, has opened a course of lectures on social hygiene.—Dr. James R. Martin has been commissioned major, M. C., N. G., Pa., and assigned to duty with the First Infantry.—Dr. Harry A. Schatz has been commissioned first lieutenant in the Pennsylvania Reserve Militia.—Dr. Lawrence F. Flick has been elected president of the newly organized American Catholic Historical Society.—Dr. Horace B. Anderson has been appointed chief of the genito-urinary clinic at Phipps Institute, by the state commissioner of health.—Dr. Louis Schwartz, who for the past four and one-half years has been in charge of the medical department of the immigration service at this port, has been transferred to Ellis Island. Dr. Dana E. Robinson, who has been connected with the War Risk Insurance branch at Cincinnati, has been appointed to take Dr. Schwartz' place.

TENNESSEE

Personal.—Dr. George C. Thomas has been appointed health officer for the city of Greeneville.—Dr. Walter S. Nash has been appointed chief of the medical staff of the Knoxville General Hospital.

Society Meetings.—At the annual meeting of the Sullivan-Carter-Johnson County Medical Society, December 3, the following officers were elected: president, Dr. Wiley W. Vaught, Shouns; vice presidents, Drs. George E. Campbell, Elizabethton, Thomas F. Staley, Bristol, and James R. Butler, Mountain City, and secretary-treasurer, Dr. William K. Vance, Bristol.—At the annual meeting of the Memphis and Shelby County Medical Society, held at Memphis Country Club, December 18, Dr. J. Lucius McGehee was elected president; Dr. Julian B. Blue, vice president, and Dr. Joel J. Hobson, secretary-treasurer, all of Memphis.—Chattanooga Medical Association, at its annual meeting, December 5, elected Dr. William H. Cheney, president; Dr. Willard H. Steele, vice president, and reelected Dr. Hiller P. Larimore, secretary and treasurer.

CANADA

Released After Long Imprisonment.—Hon. Dr. Henri Severin Beland, St. Joseph de Beauce, Que., member of the Dominion House of Commons, returned to Canada, recently, after several years' imprisonment in a prison camp near Berlin.

Rockefeller's Donation to Medical Education.—Of the \$5,000,000 said to have been donated by Mr. John D. Rockefeller to the medical colleges of Canada, President Falconer and Dean Clark of the medical faculty of the University of Toronto say that they have had no official notification up to this time. In Ottawa, great interest has been manifested in the announcement, coming as it does on the renewed discussion of the removal of Queen's Medical College from Kingston to Ottawa. The Manitoba Medical College, the third largest in the dominion, expects to get at least \$1,000,000 of the donation, while the Western at London, Ont., will lay its claims before the Rockefeller Foundation so that it may receive its share.

GENERAL

Bequests and Donations.—The following bequests and donations have recently been announced:

Toronto General Hospital, a donation of \$250,000, by Sir Joseph Flavelle, chairman of the hospital board of trustees.

Rockefeller Institute for Medical Research, New York City, \$1,000,000 by the will of the late Jacob D. Schmidlapp.

American Section of the German Red Cross, a check for 2,500,000 marks donated by relief committees in the United States for the benefit of tuberculous and undernourished German children.

Senate Passes Bill for Treatment of Tuberculous.—On January 5, the senate unanimously passed the bill permitting civilian employees of the United States government who may be stricken with tuberculosis to enter hospitals already established by the Army and Navy and Public Health Service. Civilian employees of the government will primarily, receive treatment in Public Health Service hospitals but, in emer-

gency, may go to Army and Navy hospitals. The bill now goes to the House of Representatives.

Appropriation for Research Work.—The Trustees of the American Medical Association have made an appropriation of money to further meritorious research in subjects relating to scientific medicine and of practical interest to the medical profession, which otherwise could not be carried on to completion. Applications for grants should be sent to the Committee on Scientific Research, American Medical Association, 535 North Dearborn Street, Chicago, before Feb. 1, 1920, when action will be taken on the applications at hand.

The Index Catalogue of the Surgeon-General's Library.—Volume 1, 3rd series, dated Aug. 1, 1918, covering the titles included under A-Army, has just appeared. The total number of volumes to date in the previous series is thirty-eight. The complete series, including the present volume, lists 349,313 author titles, including 178,000 volumes and 319,497 pamphlets. It also includes 309,499 book titles and 1,186,271 periodical articles—certainly an extensive accumulation of medical literature. The Surgeon-General's library itself includes 230,559 volumes, bound and unbound, and 352,523 pamphlets.

Red Cross Appointments.—The following appointments to the medical department of the League of Red Cross Societies are announced: Prof. George Chandler Whipple of Harvard University, chief of the division of sanitation; Col. Francis L. Langley, assistant chief; Dr. Thomas R. Brown, Johns Hopkins University, Baltimore, chief of the division of medical information and medical publication; Miss Alice Fitzgerald, chief of the division of nursing; Dr. George C. Shattuck of Harvard University Medical School, Boston, chief medical secretary, and Col. Henry A. Shaw, M. C., U. S. Army, in charge of the field work of the league in the prevention of communicable diseases in eastern Europe. Colonel Shaw will have as assistants, Lieut.-Col. George Fordham, M. C., U. S. Army, and Major S. H. Dunn, S. C., U. S. Army.

Red Cross and Order of St. John Unite.—An agreement has been signed by the Red Cross Society and Order of St. John by which the joint working of the joint corporations which led to good results during the world war will continue during peace. Under the agreement, a joint council has been appointed consisting of an equal number of members of each body and to this council is given the general control of the work of the two corporations. The matters which it is expected to bring under the immediate attention of the joint council are the care of the sick and wounded; such care as may still be necessary for prisoners of war; the care of those suffering from tuberculosis; child welfare; work parties to provide the necessary garments, etc., for hospital and health institutions; assistance required in all branches of nursing, health and welfare work, and home service ambulance work.

Physicians Desire Free Transportation.—The Cummins Bill providing for the return of the railroads to their owners, as finally passed by the Senate, does not contain the provision forbidding the use of free transportation to railroad surgeons. Such provision was contained in the Esch Bill as it passed the House, and prohibited free transportation to physicians and lawyers, "unless they devoted the principal part of their time to the railroad service." This provision of the Esch Bill was the occasion for wide-spread protest on the part of railroad surgeons and of local physicians for railroads who are called on in emergency to render medical aid in connection with the railroad service. The subject now will be determined by the Conference Committee appointed to adjust conflicting portions of the Cummins Bill and the Esch Bill between Senate and House. If the Conference Committee recognizes the hundreds of protests that have come to senators and members of the House, it is likely that this objectionable feature of the Esch Bill will be stricken out by the committee.

Regulation Proposed for Wood Alcohol.—State authorities, when fatalities occur, may prosecute for manslaughter and murder persons charged with selling wood alcohol for beverage purposes. However, additional legislation to safeguard the use of the poison will be recommended to Congress by the commissioner of internal revenue. The character of the proposed legislation has not yet been defined, but it is probable that it will be to place a tax on the manufacture and sale of wood alcohol, subjecting it to the restrictions which govern the manufacture and sale for nonbeverage purposes of ethyl alcohol, and requiring the holding of permits by those engaged in the traffic. There is no provision

in the internal revenue laws or in the National Prohibition Act regulating or affecting the manufacture, sale or distribution of wood alcohol, and the commissioner has no authority under present laws to regulate or restrict its use. The bureau of chemistry of the department of agriculture also has no effective control over the distribution of wood alcohol under the Pure Food and Drug Act, and new legislation is necessary if the federal government is to prohibit the use of wood alcohol as a beverage.

FOREIGN

The Nobel Prize in Medicine Not Awarded.—The Nobel prize in medicine has not been awarded since 1914.

Influenza in Spain.—Influenza is reported to have reappeared in Santander, Valencia, and other towns and to have caused many deaths.

Lepers Return Thanks.—A colony of lepers at Tarafangana, Madagascar, in a letter recently received, pays testimony to the relief extended by the American Red Cross.

Osler's Body Cremated.—The body of Sir William Osler, who died, December 29, was cremated, January 2. The urn containing the ashes will be taken to Oxford, and probably forwarded to his birthplace in Canada.

Lectures Before the Royal College of Surgeons.—The Thomas Vickery lecture was delivered by Sir John Tweedy, December 2, on "The Surgical Tradition," and the Bradshaw Lecture by Sir Charles Vallance, on "Surgery of the Heart."

Plague in Constantinople.—The *Wiener klinische Wochenschrift* quotes a press item from Saloniki to the effect that plague has appeared in Constantinople and the government of Greece has declared a four-day quarantine for travelers arriving from Constantinople.

Yellow Fever in Mexico.—Press reports state that an epidemic of yellow fever is reported in many cities and towns in Yucatan, Campeche, Chiapas, and Oaxaca, and that quarantine has been established at Tampico against Salina Cruz, Progreso, Frontera and other ports.

Personal.—Sir Donald MacAllister, superintendent of the British General Medical Council, has been invested by President Poincaré, with the Cross of the Commander of the Legion of Honor.—Surg.-Gen. Sir Alfred Keogh and Sir Almoth E. Wright have had the honorary degree of doctor of science conferred on them by the University of Leeds.

League of Dispensing Physicians in Switzerland.—The *Correspondenz-Blatt* states that the physicians who dispense their own drugs in the by-ways of Switzerland's mountain fastnesses have combined to form a league of dispensing physicians to maintain their rights, and combat abuses, such as the sale of drugs by incompetent persons, and to obtain the advantages of collective purchasing, etc. The officers of the league include Dr Trösch of Biglen and Dr. Schaad of Herzogenbuchsee.

Deaths in the Profession Abroad.—Dr. Troisier, professor *agrégé* of clinical medicine at the University of Paris.—Dr. J. Hoffmann, professor of neurology at the University of Heidelberg.—Dr. K. Moeli, professor of forensic medicine at the University of Berlin.—Dr. A. Onodi, professor of laryngology at the University of Budapest, author of numerous works on the anatomy, physiology and innervation of the throat, aged 62.—Dr F. Di Donato, a physician of Rome who took the leading part in organizing mountain and seashore colonies for weakly children.

Typhus Relief in Poland.—For purposes of administration, Poland has been divided into six districts with headquarters, respectively, at Warsaw, Lodz, Kielce, Lublin, Lonzia and Lwow. The active operations for the elimination of typhus and other infectious diseases are being handled by the central committee of the ministry of public health, which consists of Col. Harry L. Gilchrist, M. C., U. S. Army, and Drs. Viktor Hyszkiewicz, and Ludwik Rajchman of the ministry of public health of Poland. Departments of propaganda, transportation, statistics, hospitalization, quarantine, finance and schooling have been established and a Polish official has been placed in charge of each department. Each district is divided into counties and at the head of each county is a medical officer of health appointed by the minister of public health. Lieut.-Col. Lee R. Dunbar, M. C., U. S. Army, has been appointed to take charge at Lublin; Lieut.-Col. Edward C. Register, M. C., U. S. Army, at Lwow, and Major Willis P. Baker, M. C., U. S. Army, at Kielce. These officers are closely associated with the Polish district medical officers and will conduct activities in cooperation with them. The

personnel of the Polish Typhus Relief Expedition consists of twenty-two officers and 420 men with thirty-one trainloads of supplies, including 10,000 beds, equipment for 40,000 beds, 1,000 tons of soap, 50 tons of washing soda, 1,000,000 suits of underwear, all the mobile laundries and sterilizers of the American Expeditionary Forces, 320 ambulances, 320 touring cars, and 160 heavy trucks, a large quantity of drugs and other supplies purchased from the American Army in France, five complete hospital trains, and sixty-eight cars of American Red Cross supplies. Experts are setting up mobile steel laundries in eight of the large cities to provide cleansing facilities for the poor and needy. Hospital repair and construction units are at work in two of the sanitary bases of the worst infected districts. Four field columns, each of twenty enlisted specialists under commissioned officers of the Army are supervising the bathing and delousing at a rate of 800 each, daily. Hospitalization and quarantine operations are being conducted in many places in the south and east of Poland, and American property purchased by Poland is being conveyed from the warehouse in Warsaw to towns and communities designated at the rate of about ten truck loads a day. Word has been received from Col. Harry H. Snively, director of field operations, that at Lemberg, 50,000 people are waiting to be bathed and deloused. Five medical officers have been assigned to the quarantine station and military cordon, along the eastern border of Poland, and a strict quarantine is being placed along the border to prevent the large influx of refugees into Poland, before having been bathed and deloused.

The German Inhumanity at Lille.—THE JOURNAL mentioned at the time the protest signed by Calmette and four other members of scientific organizations who had remained at Lille during the long occupation by the Germans, and witnessed the "actes de barbarie" which they specified, saying in conclusion: "The high command in Germany willed the war, but the people in arms approved it, and resolutely waged war with the most ferociously cruel means, even the physicians with the army doing the most odious acts without a word of excuse, regret or pity." (THE JOURNAL, Dec. 28, 1918. Also in Paris Letter, March 8, 1919, p. 742). The *Deutsche medizinische Wochenschrift* of April 10, 1919, related that the matter was brought up in the Berlin Medical Society, and Calmette's protest and the resolutions voted thereon by the Académie de médecine at Paris were discussed. Dr. Fuld offered a resolution that the society should go on record as expressing its regret ("—das tiefe Bedauern —") at such happenings as were specified in the Calmette protest, but his suggestion was opposed by Orth and others, the speakers saying that there was no proof of the truth of the statements made by Calmette, and no voting should be done on a matter of which only one side had been presented. However a committee was appointed "nach einer ungezügelter 1 stündigen Geschäftsordnungsdebatte—" to report after obtaining an official copy of the resolutions that had been adopted by the Académie. The *Deutsche medizinische Wochenschrift* of Nov. 6, 1919, relates that this committee recently presented its report. It was in the form of a resolution which was adopted without a dissenting voice "—widerspruchslos angenommen." The members of the committee were Fuld, Kraus, Krause, Morgenroth and Schwalbe, the latter the editor of the *Deutsche medizinische Wochenschrift*. The resolution reads:

"Die Berliner medizinische Gesellschaft ist nicht in der Lage, über die Erklärung der Liller Professoren und der Akademie der Medizin sowie über die deutsche Rechtfertigungsschrift, 'Lille unter deutscher Verwaltung und die Kritik des Gegners', zu entscheiden. Sie steht aber nicht an, offen zu erklären, dass sie alle inhumanen Handlungen auf das schärfste missbilligt, wo, wann, und von wem sie begangen sein mögen. Diese Stellungnahme entspricht dem von der deutschen Ärzteschaft stets hochgehaltenen Geist der Medizin, jenem wahrhaft internationalen Geist, dem wir huldigen, dessen Anerkennung wir aber auch bei allen anderen Aerzten, gleichviel welchem Volke sie angehören, voraussetzen."

"The Berlin Medical Society is not in a position to pass judgment on the Manifesto of the Lille professors and the Académie de médecine and on the published justification issued by the German authorities, entitled 'Lille under German Rule and the Criticism of the Foe.' But the society does not hesitate to declare openly that it condemns in the most unqualified manner all inhuman actions, wherever, whenever, and by whomsoever they may be committed. This attitude corresponds to the spirit of medicine always held high by the German medical profession, that really international spirit to which we are loyal and to which we assume all other physicians are loyal wherever they may be and to whatever nation they may belong."

Government Services

Personnel of the Medical Department

For the week ending January 2, the Medical Corps contained 2,193 officers; the Medical Reserve Corps contained 4,249, an increase of eleven over the previous week.

MEDICAL OFFICERS, U. S. NAVY, RELIEVED FROM ACTIVE DUTY

<i>ARKANSAS</i>	<i>TEXAS</i>
Arkadelphia—Brown, C. C.	Houston—Flickwir, A. H.
<i>INDIANA</i>	<i>UTAH</i>
Indianapolis—Mitchell, E. II.	Salt Lake City—Marshall, H. L.
<i>LOUISIANA</i>	<i>VIRGINIA</i>
Spring Hill—Browning, B. L.	Covington—Gardner, F. P.
<i>MISSOURI</i>	<i>WISCONSIN</i>
Kansas City—Walker, J. C.	Racine—Colbert, C. N.

Cuban Order for Colonel Havard

President Menocal of Cuba has conferred the Cuban Order of Military Merit on Col. Valery Havard, M. C., U. S. Army, retired, in recognition of his work in sanitation in the Cuban Army.

Historical Division of Medical Department

A historical division, which will handle all matters pertaining to the medical and surgical history of the world war, has been created in the office of the Surgeon-General. Col. Charles Lynch, M. C., U. S. Army, has been designated as chief of the department and is assisted by Drs. Louis C. Duncan, M. C., U. S. Army, Raymond C. Turck, M. C., U. S. Army, and contract surgeons Casey A. Wood and Roy McAfee.

Hospital Ship Launched

The U. S. Hospital Ship *Relief* was launched at the Philadelphia Navy Yards, December 23, and was christened by Mrs. William C. Braisted, wife of the Surgeon-General of the Navy. The vessel is of 10,000 tons displacement, 433 feet long, has a speed of 60 knots, and a capacity for 500 patients with complete operating room and hospital equipment. An appropriation of \$3,250,000 was made by Congress for the construction of this ship.

Examination for Army Medical Corps

The Surgeon-General of the Army announces that preliminary examinations for appointments in the Medical Corps, U. S. Army, will be held March 15, 1920, at various points throughout the United States, in the Philippine Islands, Hawaiian Islands, Panama Canal Zone, Porto Rico, France, Germany and Siberia. The vacancies in the Medical Corps now amount to about 725 and since the armistice, resignations have been accepted at a rate of about twelve a month. The requirements are that the applicant shall be a citizen of the United States, between 22 and 32 years of age, a graduate of a medical school authorized to confer the degree of doctor of medicine, and that he shall have had at least one year postgraduate hospital internship, the latter requirement being waived in the case of those who have served as commissioned officers for at least one year during the world war.

Awards of Distinguished Service Medal

The Distinguished Service Medal has been awarded to the following officers of the Royal Army Medical Corps:

Major Gens.—Sir Robert Jones, eminent orthopedic surgeon and chief of Division of Orthopedic surgery, British army. Placed at disposal of medical service of A. E. F. his eminent talents and broad experience in standardizing methods of treatment for sick and wounded and took active personal interest in class instruction of American medical officers.

Sir Anthony Bowlby, while serving with the B. E. F. in France devoted his time and energy toward cooperating with and unreservedly placing at disposal of the A. E. F. his eminent talents, broad experience and knowledge of general conditions in preventing wastage among our forces from wounds and disease. His research work in wound bacteriology and evacuation resulted in saving many lives among our sick and wounded.

Cuthbert Wallace, while serving with the B. R. F. in France, devoted time and energy toward promoting standard methods for efficient treatment of American sick and wounded.

Sir Henry Tuompson, director of the medical service, 1st British Field Army in France. Placed time and energy at disposal of A. E. F. The sanitary school maintained in his army for teaching front-line medical requirements was utilized for instruction of American medical officers sent to him by classes. The observation and experience gained by these student officers under his able supervision and guidance eventually resulted in saving lives of many American wounded.

Report of the Surgeon-General, U. S. Army, for 1919

This report appears in two massive volumes containing in all 2,167 pages and covering the experience of the medical department of the United States Army for the year 1918. It records the expansion of the army from a group of less than 100,000 men to one of 3,500,000; transportation of more than 2,000,000 soldiers, with all necessary equipment and supplies, to Europe and the safe return of the vast majority to this country. In his report to the Secretary of War the Surgeon-General says: "It was only by the concentrated and combined efforts of the country, as a whole, that the undertaking was successfully accomplished." "Practically the entire medical profession of the United States," he says, "became the medical department of the army and navy." In his letter he recapitulates the organization of the army and the construction of hospitals for the care of the sick. The effect of the influenza epidemic plays a leading part. In summarizing his letter of transmission, Surgeon-General Ireland says:

1. The total number of admissions during 1918 for diseases for officers and enlisted men, American and native troops, was 2,422,362; for ordinary injuries, 182,789; and for battle injuries, 227,855.

2. The total number of deaths from disease was 47,384; from wounds received in battle (cases treated in hospital), 13,735; killed in action, and lost at sea, 34,359; from ordinary traumatism, 3,500.

3. Including the deaths from 1917, there were 50,714 from disease and 52,423 as the result of injuries of various kinds, including wounded, killed in action, and lost at sea.

4. The total number of days lost from disease for the year was 40,692,302; from battle injuries 12,545,442; and from ordinary injuries 3,687,060. The average number of men absent each day of the year on account of sickness and injuries was 155,957. Seventy-one per cent. of the time lost was caused by disease, 6 per cent. by ordinary injuries, and 22 per cent. by battle injuries.

5. Since the soldiers of the Civil War for the United States Army were drawn only from the Eastern and Northern States, with a few from the Western States, if other conditions had been the same, the rates should have been lower for the first two years of the Civil War than the corresponding rates for the Army in 1917-1918, which was made up of troops from all sections of the country, including the colored.

6. For the first two years of the Civil War, as compared with 1917-1918, the admission and the death rates for disease was three and one-half times as high.

7. Comparing the rates for the Spanish-American War and the Philippine Insurrection, 1898-1899, with those for 1917-1918, the admission rate in 1898-1899 was a little over twice as high and the death rate about 20 per cent. higher.

8. The admission rate for the specific fevers and the diseases of the intestines (including diarrhea and dysentery) was twenty-nine times as high in 1861-1862 as in 1917-1918, and the death rate was 258 times as high.

9. For these diseases for 1898-1899 the admission rate was twenty-four times as high and the death rate 125 times as high as in 1917-1918.

10. For the acute infectious diseases (excluding influenza, pneumonia, and the common respiratory type) the admission rate for 1861-1862 was practically the same as in 1917-1918. The death rate in 1861-1862 was two and one-half times as high as in 1917-1918, but 8 per cent. lower in 1898-1899 than in 1917-1918.

11. The respiratory type, including influenza, pneumonia and the common respiratory diseases, had higher admission and death rates for 1917-1918 than for either 1861-1862 and 1898-1899.

12. Influenza, probably associated with virulent pneumonia, was epidemic during the latter part of 1917 in this country and in Europe. The epidemic wave declined during the cold, dry, winter weather, and increased again in the spring, after which time it again declined, but continued throughout the summer to rise again to the high point in the autumn months.

13. Influenza, combined with pneumonia and respiratory diseases, caused 17.33 per cent. of the total admissions for

diseases, and 82 per cent. of the total deaths. This type of disease was the most important cause of loss of time.

14. All of the epidemic diseases other than influenza, pneumonia and the common respiratory diseases declined after the first part of 1918. The rates for most of these diseases were lower during the first part of 1918 than during the latter part of 1917.

15. Approximately 5.6 per cent. of the men who came into the military service from civil life had a venereal disease.

16. Approximately 7.4 per cent. of all the men in the army were detected with a venereal disease some time prior to their leaving the United States.

17. Of this number three fourths had contracted the infection prior to coming into the military service.

18. Two thirds of all that were detected with a venereal disease in the entire army, during 1917-1918, brought the infection in from civil life.

19. The occurrence rate in Europe and in the United States of new cases of venereal diseases in the army was approximately the same.

20. The negroes in the United States had an admission rate for venereal diseases of seven times as high as the whites.

21. Practically 70 per cent. of the negro soldiers either had a venereal disease when brought in from civil life or contracted an infection during 1918.

22. Of the average number of colored soldiers who served in the United States during the year 1918, 4.6 per cent. had to be discharged for a venereal disease.

23. The rate for venereal diseases for the colored in countries other than the United States was slightly higher than the rate for the whites.

24. The nativity rates for venereal diseases for the negro soldiers from the South, as compared with the white soldiers from the South, show that the negro had approximately four times as much venereal disease as the whites from the same section.

25. The nativity rates for the white soldiers from the various sections of the country show that the white soldiers from the South had higher rates for venereal diseases than the white soldiers from other sections of the country.

26. The nativity rates show that the white soldiers from the South have higher rates for measles, mumps, cerebrospinal meningitis, bronchopneumonia, lobar pneumonia and influenza, and that the soldiers from the West and Northwest have higher rates for scarlet fever, diphtheria and German measles.

27. The soldiers from the Eastern States had lower nativity rates for mumps and measles, but the soldiers of the West and Northwest had lower rates for influenza, bronchopneumonia and lobar pneumonia and meningitis. This low standing of the latter states may possibly be due to the recent immigration to them.

28. The negroes have lower admission rates than the whites of the country at large for measles, German measles, scarlet fever, diphtheria and influenza, and much lower rates for these diseases than the whites from the South.

29. The negroes have higher rates for meningitis and tuberculosis than the whites from the entire United States, but approximately the same rates for them as the whites from the South.

30. The incidence rate for all forms of pneumonia, both primary and secondary, was nearly three times as high for the colored as for the whites of the entire country. The death rate was more than twice as high, but the case mortality was 20 per cent. lower.

31. As compared with the whites of the South, the negro had a nativity rate for the combined pneumonias of more than twice as high.

Following his letter of transmission, the Surgeon-General presents the statistics covering the health of the army; a tabulation of the strength of the army; a complete discussion of all of the large camps in the United States, thirty-seven in number; a vast department on infectious diseases occupying pages 618-1015, discussing the infectious diseases, as a whole, and as they affected various parts of the service; a separate discussion of the work of each of the special divisions of the Surgeon-General's Office, and, finally, the work of the expeditionary forces abroad. A significant feature of the report, as a whole, is the lack of personal mention of any medical officer in relation to the service done. This appears to have been the custom of similar reports in previous years. The extent of the compilation and its value as a reference work are, of course, permanent. The Surgeon-General's Office is to be congratulated on having issued such an important document in such good order and with such facility.

Foreign Correspondence

PARIS

Dec. 4, 1919.

Important Modifications of Disability Pensions

In a former letter (*THE JOURNAL*, May 17, 1919, p. 1479), I reported certain increases in military pensions. Since then a number of worth-while reforms in the military pension system have been introduced. For example, as regards the furnishing of proof that the wound or the disease in question was actually contracted in the service, the new law establishes the "presumption of origin" in favor of applicants for pension. This applies not only to the term of actual service but, if it is a question of disease, also to the six months following the demobilization. It suffices, in order to take advantage of the presumption of origin, that the applicant shall have made, within the time limit of six months, written application to the regional director of the army medical department. The burden of proof as to whether the wound or the disease in question was contracted in the service or not rests on the state.

On the other hand, the number of pensions to be allowed having been settled, there seemed to be a need of doing away with some of the formalities complicating payment. For instance, according to the laws and regulations as they formerly existed, the army medical department acted in the matter of pensions in a purely advisory capacity. Henceforth, it will be the duty of the army medical department to institute demands for pensions and to superintend all matters of a medicolegal nature until the decision of the pension board is reached. The personnel of the pension boards has of late been modified in such a manner as to give the weight of authority to the physicians, who formerly acted only in an advisory capacity (*THE JOURNAL*, June 28, 1919, p. 1929).

The instructions in regard to the examination of pension claims have also been simplified. The chief surgeons who act as chairmen of the pension boards have received instructions not to insist too strongly on finding the causes of the infirmities, unless there are elements in the case that might cause one to infer some cause extraneous to military service. The presentation of the hospital card of admission suffices to allow the presumption of origin to operate, when it is a question of disease, or to establish such origin if it is a wound that is being considered. The examination of pension claims is conducted now by two physicians instead of five as formerly. These two physicians devote themselves exclusively to the expert survey of pension claims. An interesting modification is the establishment of local sessions of the pension boards throughout the country. Applicants, especially those who are untransportable, may take advantage of these sessions and be examined at home. This also makes it possible for their family physician to render them aid, as is authorized by law. The applicant may, moreover, be excused from presenting himself in person, in which case the pension board may decide the case on the basis of written evidence. The number of pensions granted by the pension boards is constantly increasing. From 8,700 in January, 1919, the number rose to 40,000 in September, 1919, and now the number has passed the 150,000 mark.

Death of Physician in Accident

Dr. Jaugeas, assistant roentgenologist in the Saint-Antoine Hospital, has just met death under distressing circumstances. He had been called to the American Hospital at Neuilly to do some roentgenologic work. While he was occupied in adjusting the Coolidge tube in order to regulate the quality of the roentgen rays, a terrible deflagration occurred and Dr. Jaugeas was electrocuted on the spot. Jaugeas had been for seventeen years Dr. Bécère's assistant in the roentgenologic laboratory of the Saint-Antoine Hospital. In 1913 he published a valuable compendium on radiodiagnosis.

Industrial Diseases and the Workmen's Compensation Law

The senate has just passed a bill that had been previously approved by the chamber of deputies which provides that certain industrial diseases shall be brought within the scope of the workmen's compensation law. The law in the form approved by the senate recognizes only two diseases as having the character of industrial diseases, namely, lead and mercurial poisoning (saturnism and hydrargyris). Provision is made, however, for the amplification of the law and the recognition of other diseases as industrial diseases. In

view of this ultimate extension of the law and also for the purpose of preventing industrial diseases, the law makes it compulsory for any physician who recognizes the existence of a disease presenting the characteristics of an industrial disease to report such to the minister of labor. For reporting such diseases, stub books are furnished physicians gratis, and reports are frankable.

The new law imposes a penalty of from 100 to 500 francs or imprisonment for from three days to six months on any one who by threats, gifts, promises of reward, or "ristourne" (underhanded rebates) on medical fees or pharmaceutical supplies made to injured workmen or to syndicates or associations, or to the heads of industrial enterprises, to insurance companies or to any other person, shall induce or attempt to induce the victims of industrial accidents or of industrial diseases to enter any clinic or any physician's office or any pharmaceutical laboratory and shall have thus attempted to deprive a workman of the liberty of choosing his physician or his pharmacist. This legislative action was taken on account of the shameful practices of a certain class of tricksters whose ranks have seemed to be growing the past few years.

A Medical Controversy

At the last general meeting of the Syndicat des médecins du département de la Seine, several members of this corporate body took the floor to attack the conduct, during the war, of certain men who are military surgeons by profession. Others went still further and preferred general charges against the army medical department, maintaining that during the war it had often shown itself inadequate to the task that rested on it. The president of the syndicat, Dr. Leredde, made the following suggestion: "The best thing to do will be to make an inquiry into the activities of the army medical department during the war, and for the Corps médical non militaire to consider the best way of reorganizing this service in agreement with the Union des syndicats médicaux." To this proposal the military surgeons by profession have replied, not without reason, that in that case the civilian physicians would be both plaintiff and judge.

The Milk Shortage in Paris and Vicinity

At no time since the beginning of the war have Paris and the department of the Seine been so inadequately supplied with milk as at present. Before the war (in 1913) 830,000 liters of milk were shipped in daily, and 115,000 liters were produced locally, which made the total daily consumption 945,000 liters. During the war and since, shipments from without, as well as local production, have continued to diminish, and, at the present time, Paris and its environs have become reduced to 473,000 liters, which is only 50 per cent. of the prewar supply. Besides, the population of Paris and its suburbs has increased considerably during the last few years, so that if the present supply of milk were divided equally among the inhabitants the per capita apportionment would be scarcely one-tenth liter.

M. Martel, chief of the veterinary and public health service of Paris and the department of the Seine, has recently called the attention of the Academy of Medicine to this state of affairs, pointing out at the same time the causes. This unfortunate situation is due, he states, to the systematic destruction of milch cows in the regions invaded by the enemy; to the misuse of milk in order to obtain certain derivative products by reason of the high prices secured for these (which explains why in the devastated regions of France milk is selling at 70 centimes [13 cents] per liter wholesale, while butter is sold for 18 francs per kilogram [\$1.58 per pound]); to last summer's drouth, which caused an advance in the prices of various kinds of cow feed; to aphthous fever, which has been prevalent in numerous dairy sections of the country, and finally to the greed of certain producers who take advantage of the exigencies of the situation to boost the prices.

How is this milk shortage to be remedied? In the first place, as soon as spring opens, milch cows at reasonable prices should be placed at the disposal of the farmers of the devastated regions, while, at the same time, the carrying out of the provisions of the peace treaty with Germany should be hastened (especially as regards the surrender of the stipulated number of milch cows, is doubtless meant.—Ed.). Furthermore, the order prohibiting the use of fresh milk and cream in cafés, tea rooms, etc., as reported in a previous letter (*THE JOURNAL*, Nov. 15, 1919, p. 1539) should be strictly enforced. It would perhaps be advisable, in order to enforce the requirements of this order, to prohibit in such

establishments the sale of milk in any form whatsoever. It would also be well to prohibit, or at least to control, the manufacture of cream cheeses, the extraordinarily high prices of which permit the manufacturers operating in Normandy to offer to milk producers prices such as the milk companies supplying the cities cannot hope to secure. Likewise, it would seem in place to prohibit on the market the listing of the so-called "extra" grade of veal, the production of which requires an excessive consumption of milk. An appeal must also be made to the conscience of the heads of families in order that the use of preferential milk tickets may be confined to those for whom milk, by reason of age or sickness, is an actual necessity.

Professor Pinard, also, has protested against the custom that prevails in certain sections of feeding young calves large quantities of milk, giving a single animal as much milk as five or six patients or fifteen babies would require.

For the study of the milk question the Academy of Medicine has appointed a commission composed of Professors Pinard and Ribemont-Dessaignes, Dr. De Fleury and M. Martel. At the instance of this commission, the Academy of Medicine has passed a resolution embodying four lines of action which it recommends be taken to cope with the situation: 1. The sale at cattle markets, abattoirs or meat shops of milk-fatted calves, so-called "veau de lait," should be prohibited. 2. The manufacture and sale of cream cheeses should be suppressed. 3. The order of Oct. 10, 1919, with respect to the use of fresh cream and milk, should be strictly enforced. 4. The prefecture of the department of the Seine should be requested to study out a system by which patients could secure without fail fresh milk at any time, and more particularly the prefecture should be asked to consider the feasibility of fresh milk being kept on hand by pharmacists and sold to those who produce medical prescriptions for it.

A Maternity Hospital for Unmarried Mothers

M. Herriot, the mayor of Lyons, has induced the general council of the department of the Rhone to appropriate the sum of 200,000 francs for an exceedingly humane project, namely, the establishment of a secluded maternity hospital which will be open without distinction to all unmarried prospective mothers. Thus far it has been equipped with forty-five beds.

LONDON

Dec. 17, 1919.

A Higher Qualification in Ophthalmology

The Council of British Ophthalmologists has issued a report on examinations in ophthalmology. At present there are examinations of two classes: (1) that in which ophthalmology forms part of a higher examination in medicine and surgery, as for the M.D. or M.S. of the University of London, and (2) that in which qualified physicians are examined independently of any examination in general medicine and surgery, as, the diploma in ophthalmology of the University of Oxford. The first examination in ophthalmology as a special subject was established by the Royal College of Surgeons of Edinburgh in 1883. In the examination for the fellowship, ophthalmology is compulsory. At the University of London, ophthalmology has recently been recognized as a special branch of the M.S. degree, the candidate having had to spend at least two years in the study and practice of ophthalmology at an approved school for one year at least subsequent to obtaining the M.B., B.S., and to hold during this time for at least six months an appointment in the ophthalmic department of a recognized general or ophthalmic hospital. A circular letter was sent to the principal hospitals of the United Kingdom asking what professional qualifications were required for candidates for the post of ophthalmic surgeon. Most of them required higher qualifications in surgery, but these often did not imply a special knowledge of ophthalmology. Only five required this. In the present higher examinations there is seldom any adequate test of a candidate's knowledge of ophthalmology. The report concludes with the recommendation that the universities and colleges should provide a special examination in ophthalmology for those who propose to devote themselves to it. Ophthalmology should be one of the optional subjects which a candidate can elect to be examined in for the degree of Master of Surgery of a university or for the fellowship of a college of surgeons. Before presenting himself, the candidate should have studied ophthalmology for at least two years and held recognized ophthalmic appointments for one of these years. The special examination in ophthalmology should be written, oral and practical, and should comprise

anatomy, pathology, optics, systematic and clinical ophthalmology, and operative surgery.

Graduate Medical Teaching in London

The problem of graduate medical teaching in London continues to exercise the leaders of the profession. In a joint letter to the *Times*, Adami, Clifford Allbutt, Dawson, Arbuthnot Lane, Makins, Osler, and Rolleston point out that America and England are the only countries mutually interested in each other's history—so interested that the students of each are likely to seek graduate instruction in the other country—whereas every civilized country is interested in the science of health and is anxious to gain fresh knowledge wherever it can be found. Before the war, Germany and Austria, by their skilled and subtle propaganda, developed by enlightened government subsidy, had hypnotized the world into believing that medical graduates could complete their knowledge only in those countries. Americans, Frenchmen and even our own ambitious physicians took it as a matter of course that they must "finish" by sitting at the feet of the Teuton, who fed them with a *réchauffé* of what he had gleaned from England, France and America; for with few and rare exceptions no striking advance in medicine and surgery can be claimed by Teutonic workers. The war closed the German schools to the Allies, and very quickly it was discovered that we had better material at home if it could only be made available. Of this there has been convincing evidence in the year now ending. Soon after the armistice, the Fellowship of Medicine was founded to promote friendly relations between the members of the profession in the allied nations, and a graduate medical course was arranged in London to meet the wishes of a large number of medical officers of the dominions and the United States. The course was so successful that it is still maintained. But something more permanent is needed. The Post-Graduate Medical Association has been amalgamated with the Fellowship of Medicine. The immediate duty of the teaching hospitals is to teach undergraduates. Any satisfactory scheme for advanced training for graduates must provide not only for visitors from abroad but also for the home graduates who wish to extend their knowledge or to undertake research. It will therefore be necessary to have in London one or more graduate teaching hospitals, including laboratories. It is hoped that this proposal will receive the support of the board of education and the University Grants Committee. The object of the writers is to inform the public of what is needed and to enlist its sympathy. The project is of imperial significance, but cannot be accomplished by the medical profession and the staffs of the teaching schools without substantial help. Time will not permit of the building and equipment of a new hospital for the purpose. Before it could be finished, the students to be provided for would have wandered elsewhere in search of what they need. Before we could be ready, thousands would have found their way to Teutonic centers, which will make frantic efforts to regain what they have lost. In a single year American students alone spent more than \$200,000 in Vienna. The writers therefore urge that the government should enable one or two large general hospitals in London to equip themselves exclusively for graduate work and that these should by cooperation with other medical schools provide themselves with such a staff as to be second to none, if not indeed superior to any in the world.

Insurance Scheme for Panel Physicians

The medical committees under the national health insurance act are devising an insurance scheme for providing physicians with certain benefits. It is urgently needed, as cases of distress are often reported. If a reservation of 12 cents per insured person were made, this would give, on an insured population of 14 millions, an annual income of \$1,750,000. It is proposed to form a society and to ask the government to pay into it a certain sum, either 12 or 24 cents a year, in respect to each insured person. It would be managed by a committee of physicians and actuaries. The benefits proposed are: (1) \$500 to cover funeral and similar expenses; (2) a sum of money to be paid when a member reaches the age of, say, 65, or previously if death occurs; (3) a pension payable from a fixed age for the remainder of life; (4) sums to meet the education of children, temporary financial difficulties, the purchase of a practice, a house, etc.; (5) money to be paid to a member on leaving the organization through ceasing to be a panel physician before reaching the fixed age; (6) a lump sum or a pension payable to a member compelled to retire owing to ill health before he becomes entitled to the ordinary scale of pension.

MEXICO CITY

Dec. 21, 1919.

The Academy of Medicine

At the meeting held on the third instant by the Academy of Medicine, the guest of honor was Dr. Theodore C. Lyster, colonel (retired) of the Medical Corps of the United States Army and a member of the yellow fever commission of the Rockefeller Foundation. At the same meeting there was exhibited one of the preparations of *Leptospira icteroides*, and Dr. Cervera described in detail Noguchi's scientific work, discussing especially that part relating to the etiology of yellow fever. In his opinion this question has been solved, as the only thing remaining to be done is to have other workers confirm Noguchi's statements which comply fully with Koch's postulates relative to the discovery of pathogenic organisms, and in addition other requirements have been fulfilled which were unknown in Koch's epoch. After other persons discussed the work done in Mexico to eradicate yellow fever, Dr. Lyster spoke in Spanish to describe the work he has performed in different places in Central and South America and the results obtained in his campaign against this disease. In concluding he expressed his thanks to the Academy for the many attentions he had received, which showed that among the scientists of this country there is no ill feeling towards the United States. In the meeting of the 17th, on motion by Dr. Monjarás, Dr. Hideyo Noguchi was elected unanimously, honorary member of the Academy in recognition of the meritorious services rendered by him to science and humanity.

Yellow Fever

This disease is still present in the state of Yucatan and it seems even to be spreading as the board of public health has reported one case in the port of Campeche and placed that city in quarantine. On the other hand, it has been confirmed that the cases that occurred in the southern part of the state of Sonora were of malaria and not yellow fever.

Noguchi in Mexico

Dr. Noguchi has just landed at the port of Progreso from which he will proceed to Merida in order to carry on confirmatory studies of his discovery of *L. icteroides* and to try on a larger scale the curative properties of the specific serum prepared by him. It is expected that his efforts may contribute to eradicate yellow fever from Yucatan and amplify our bacteriologic and therapeutic knowledge of this disease.

Personal

On December 11 Dr. Gregorio Mendizábal celebrated the fiftieth anniversary of his entering the practice of medicine, receiving on this occasion many tributes. The Association "Escobedo" held a meeting in his honor and finally the physicians of the city of Orizaba, where he was born, have invited him to spend a few days there as their guest.—Dr. A. Lozano Garza, lieutenant-colonel of the medical corps, has been designated by the government to proceed to the United States to study with other persons the operation of the institutes devoted to the training of abnormal children.

Marriages

LEWIS WELLS JOHNSON, Asst. Surg., Lieut. (j. g.), U. S. Navy, Chelsea, Mass., to Miss Mildred E. Stevens, at Manchester, N. H., December 22.

BELLENDEN SEYMOUR HUTCHESON, V. C., Capt., C. A. M. C., Cairo, Ill., to Miss Frances Young of Kentville, Nova Scotia, December 1.

JOSEPH CLARK STEPHENSON, Norman, Okla., to Miss Alice Marie Gerlach of Woodward, Okla., December 27.

WILLIAM EDWARD MORGAN, Longmont, Colo., to Miss Venice Zajicek of West Point, Neb., November 6.

DAVID RALPH BOWEN, Philadelphia, to Miss Edith Mary Warrington of Georgetown, Del., December 29.

THURMAN ROSS BEAVER, Akron, Ohio, to Miss Lillian Catherine Arnold of Rockford, Ill., December 8.

WILLIAM EUGENE KENDALL, Oak Park, Ill., to Miss Jessie May Thorpe of El Paso, Ill., December 26.

ANDREW JACKSON CLAY, Hoxie, Ark., to Miss Enid Laveta of Hugo, Okla., December 25.

HOWARD KAYLOR, Bluffton, Ind., to Miss Ella Cary of Pennville, Ind., November 11.

Deaths

Horatio C. Wood, Philadelphia; University of Pennsylvania, Philadelphia, 1862; aged 78; successively professor of botany, therapeutics, clinical professor of diseases of the nervous system, and emeritus professor of therapeutics in his alma mater; editor of *New Remedies* from 1870 to 1873; of the *Philadelphia Medical Times*, from 1873 to 1880; of the *Therapeutic Gazette*, from 1884 to 1890; and of the *United States Dispensatory* from 1893 to 1907; president of the Pharmacopoeial Convention of the United States from 1890 to 1910; and of the College of Physicians of Philadelphia, in 1902-1903; author of standard works on materia medica and therapeutics, and nervous diseases and their diagnosis; who was given the honorary degree of LL.D. by Lafayette College in 1883, by Yale University in 1889 and by the University of Pennsylvania in 1904; died, January 3.

Mitchell Otis De Vaney * Indianapolis; Medical College of Indiana, Indianapolis, 1901; aged 40; lieutenant, M. C., U. S. Army, with services on the Mexican border and at Camp Taylor, Louisville, Ky., and honorably discharged, Jan. 9, 1919; associate medical director of the Indianapolis Life Insurance Company; formerly secretary of the Marion County health board; was drowned, December 30, when the automobile which he was driving ran over a 30-foot embankment, near Fall Creek, pinning Dr. De Vaney underneath the machine.

Thomas Jefferson B. Rhoads, Boyertown, Pa.; Jefferson Medical College, 1861; aged 82; a member of the Medical Society of the State of Pennsylvania; assistant surgeon of the 169th Pennsylvania Volunteer Infantry during the Civil War; president of the National Bank of Boyertown, and later of the Farmer's National Bank of Boyertown; president of the Boyertown Mutual Fire Insurance Company; died December 24, from heart disease.

Dwight Seymour Spellman, New York City; College of Physicians and Surgeons, Baltimore, 1889; aged 53; a member of the American Medico-Psychological Association; assistant senior physician and since 1889 a member of the staff of the Manhattan State Hospital, Wards Island; while skating at Tom's River, N. J., December 18, broke through the ice, and before assistance arrived, died from shock.

Jesse Fonda Millsbaugh, Los Angeles; University of Pennsylvania, Philadelphia, 1883; aged 64; president of the Minnesota State Normal School, Winona, from 1899 to 1904, and of the California State Normal School, Los Angeles from 1904 to 1913, and president emeritus since that time; a member of the California State Board of Education from 1904 to 1912; died December 13, from pneumonia.

George Elliot Chamberlain, South Newbury, Vt.; Dartmouth Medical School, Hanover, N. H., 1896; aged 50; acting assistant surgeon, United States Army, from September, 1898, to December, 1902, with service in Cuba and the Philippine Islands during and after the war with Spain; captain M. R. C., U. S. Army, and discharged, March 27, 1918; died in a hospital in Cambridge, Mass., December 14.

Frank W. Wyman, Stroud, Okla.; College of Physicians and Surgeons, Keokuk, Iowa, 1877; aged 71; a member of the Oklahoma State Medical Association; a surgeon in the United States Indian Service for many years, and government physician at the Sac and Fox Agency for more than twenty years; died at the home of his daughter in Detroit, December 19.

Robert Mason Fuller, Schenectady, N. Y.; Albany (N. Y.) Medical College, 1865; aged 75; a member of the Medical Society of the State of New York; said to have been the originator of the idea of administering medicine in tablet form; surgeon of U. S. Volunteers during the Civil War; died December 28.

Warren Cushman Hewitt, Xenia, Ohio; Homeopathic Hospital College, Cleveland, 1888; aged 54; a member of the Ohio State Medical Association; for sixteen years resident physician to the Ohio Soldiers' and Sailors' Home, Xenia; died December 18, from heart disease.

George A. B. Hays * Happy Jack, La.; Tulane University, New Orleans, 1874; aged 72; for many years superintendent and chief physician of the East Louisiana Hospital for the Insane, Jackson, and the Louisiana Hospital for the Insane, Pineville; died December 20.

John Houstoun M. Clinch * Danville, Ill.; University of Oregon, Portland, 1896; aged 56; a member of the medical staff of St. Elizabeth's Hospital; while driving in his automobile over a grade crossing in Danville, December 24, was struck by a train and instantly killed.

Daniel Murray Cheston, West River, Md.; University of Pennsylvania, Philadelphia, 1864; aged 76; who fractured both arms and his nose, from a fall, while visiting in Chestnut Hill, Philadelphia; died from his injuries in the Chestnut Hill Hospital, December 22.

Edwin Augustus Down, Hartford, Conn.; College of Physicians and Surgeons in the City of New York, 1887; aged 64; a member of the Connecticut State Medical Society; for ten years president of the state board of charities; died December 22, from heart disease.

Charles Albert Folsom, Epping, N. H.; Dartmouth Medical College, Hanover, N. H., 1902; aged 45; a member of the New Hampshire Medical Society and New Hampshire Surgical Club; until a year ago a practitioner of Manchester, N. H.; died December 16.

Robert Dodds * Escondido, Calif.; formerly of Chicago; Northwestern University Medical School, Chicago, 1890; aged 63; a specialist in gynecology; died in the Sanitarium Escondido, December 18, from sclerosis of the cortex with spastic paralysis.

Joseph Alexander Doyle * Greenville, Pa.; Western Reserve University, Cleveland, 1893; aged 57; lieutenant, U. S. N. R. F., and relieved from active duty, July 11, 1919; died September 5, from valvular heart disease.

Joseph Johnston Fleming, Wickenburg, Ariz.; Cleveland College of Physicians and Surgeons, 1898; aged 47; chief surgeon of the Rio Grande Mines Company; died at Pierce, Ariz., October 22, from myocarditis.

Frank Atwater Stove * Bowling Green, Ohio; Ohio Medical University, Columbus, 1904; aged 46; lieutenant, M. R. C., U. S. Army, and honorably discharged, Oct. 25, 1919; died December 18, from carcinoma.

Charles R. Rosendale, Bowling Green, Ohio; Eclectic Medical Institute, Cincinnati, Ohio, 1856; aged 87; died at the home of his daughter in Bowling Green, December 15, from senile debility.

William B. Van Note * Lima, Ohio; Medical College of Ohio, Cincinnati, 1895; aged 52; a specialist on diseases of the eye; died at Miami, Fla., December 20, from pneumonia.

William B. Ellis, Concord, Mo.; Homeopathic Medical School of Missouri, St. Louis, 1888; aged 73; a Confederate veteran; also a dentist; died December 20, from heart disease.

William Edward Hodges, Bynum, Texas (registration, Texas Fifth Judicial Board of Medical Examiners, 1901); aged 59; died December 10, while making a professional call.

Thomas A. Crawford, Rock Hill, S. C.; Hospital College of Medicine, Louisville, Ky., 1877; aged 66; a member of the South Carolina Medical Association; died November 11.

Herbert Orray Benner * Framingham, Mass.; Dartmouth Medical School, Hanover, N. H., 1896; aged 55; died in the New England Baptist Hospital, Boston, recently.

Frederick Halves, Brooklyn; Bellevue Hospital Medical College, 1870; aged 79; died at the home of his daughter in Brooklyn, December 21, from heart disease.

O. M. Norman, Roseville, Ohio; Cincinnati College of Medicine and Surgery, 1873; aged 88; a member of the Ohio State Medical Association; died December 18.

Norman L. Lee, Junction City, Ore.; Willamette University, Salem, Ore., 1871; aged 82; a veteran of the Civil War; died October 24.

Wilhelmina F. O'Connor, Denver; Denver College of Physicians and Surgeons, 1898; aged 71; died December 8, from heart disease.

Josiah W. P. Jarvis * Fairview, W. Va.; Baltimore University School of Medicine, 1895; aged 66; died December 12.

Dumont Durant Howell, Stillwater, Okla.; University of Nashville, Tenn., 1903; aged 45; also a banker; died December 6.

Carl Henry Golbeck, Chicago; University of Illinois, Chicago, 1913; aged 29; died December 21, from acute endocarditis.

Robert Sutfenfield Lipes, Hudson, N. Y.; Albany, N. Y., Medical College, 1907; aged 39; died December 9, from myocarditis.

* Indicates "Fellow" of the American Medical Association.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

MORE MISBRANDING

King's Kidney Remedy.—George L. King, Kingfisher, Okla., shipped in December, 1916, a quantity of nostrum called "King's Kidney Remedy." The Bureau of Chemistry analyzed this preparation and reported finding uva-ursi, sarsaparilla, cascara, gentian, senna, poke root, buchu, wild cherry bark, dandelion, yellow poplar, stillingia, hydrangea, and possibly, in addition prickly ash, black cohosh, golden seal and coriander. The stuff was sold under the false and fraudulent claim that it was an effective remedy for lumbago, rheumatism, sciatica, neuralgia, diabetes, dropsy and any irregularity of stomach, liver, kidneys or urinary organs, "when in truth and in fact it was not." In September, 1918, the defendant pleaded guilty and was fined \$25 and costs.—[*Notice of Judgment No. 6516; issued Dec. 29, 1919.*]

Miscellaneous Tablets.—In September and November, 1917, the United States Drug Manufacturing Co., Philadelphia, shipped a number of different tablets which the federal authorities declared were adulterated and misbranded. Acetphenetidin and Salol Tablets, when analyzed, were found to have an average shortage of acetphenetidin of over 20 per cent. and an average shortage of salol of over 18 per cent. Tablets containing Acetylsalicylic acid, Acetanilid and Caffein Citrate were found to have an average shortage of acetylsalicylic acid of 9 per cent., an average shortage of acetanilid of 9.5 per cent. and an average excess of caffein citrate of over 40 per cent. Tablets of Morphin Sulphate were found to have an average shortage of the amount claimed of over 62 per cent. Tablets of Acetanilid and Salol were found to have an average shortage of the former drug of about 11 per cent. and of the latter of over 21 per cent. In November, 1918, the United States Drug Manufacturing Co. entered a plea of guilty and was fined \$25.—[*Notice of Judgment No. 6548; issued Dec. 29, 1919.*]

Casey's Rheumatic Cure.—In October, 1917, the John H. Casey Medicine Co. of Hillyard, Wash., shipped a quantity of "Casey's Rheumatic Cure—The Great Montana Remedy" which was misbranded. The Bureau of Chemistry analyzed this preparation and found it to consist essentially of a water-alcohol solution of potassium iodid, sugar and drug extractives carrying saponin (sarsaparilla indicated), emodin, volatile oil and resins. It was falsely and fraudulently represented as a cure for rheumatism, diseases of the blood and kidneys, Bright's disease and a remedy for stomach trouble, heart trouble, and impure blood. In addition to these fraudulent claims the amount of alcohol present was falsely given and it was falsely declared to be a "Purely Vegetable Compound, Contains No Mineral," when as a matter of fact it contained potassium iodid. In February, 1919, the John H. Casey Medicine Company pleaded guilty and was fined \$25.—[*Notice of Judgment No. 6549; issued Dec. 29, 1919.*]

Miscellaneous Capsules.—In February, May and June, 1917, Joseph McManus, who did business under the name of Philadelphia Capsule Co., Philadelphia, shipped a number of articles which were declared to be adulterated or misbranded or both. Some capsules labeled "Grip Pans" were declared by the company to contain "acetanilid derivative 125 grs. to the ounce . . . phenylsal 1½ grs., salipyrine, 1 gr." The federal chemists found that these capsules contained no acetanilid derivative, phenylsal or salipyrine. They did contain acetanilid (28.15 per cent.) and the label failed to bear a statement of the quantity or proportion of this drug as the

law requires; they also contained ammonium salicylate, 37.38 per cent. and sodium bicarbonate, 25.52 per cent. Capsules labeled "Aspirin 5 grains," contained only 3.585 grains each, or a shortage of 28 per cent. "Mixed Treatment Capsules" declared to contain 5 minims of syrup ferrous iodid and 2 minims of solution arsenous and mercuric iodids, actually contained not more than 3.72 minims syrup ferrous iodid and 0.52 minim solution arsenous and mercuric iodids. "Sedative Capsules," according to the label, each contained ammonium bromid, 2½ grains, sodium bromid, 2½ grains and potassium bromid 2½ grains; actually the capsules contained less of each of the bromids than the label declared; also the boxes of capsules instead of containing 200 as labeled, contained only 172. "Codephen Capsules" according to the label, contained 3 grains of acetphenetidin each, when, as a matter of fact, they contained no acetphenetidin. The capsules did, on the other hand, contain codein, the quantities or proportions of which were not declared as the law requires. Capsules known as "Migraine, Pref. No. 2," were misbranded in that the bottle declared the presence of 200 capsules when only 186 were found and for the further reason that the capsules contained acetanilid but the label failed to give the quantity or proportion of this drug. Capsules labeled "Salol and Acetphenetidin" were misbranded in that the quantity or proportion of acetphenetidin was not declared as required. In December, 1918, Joseph McManus entered a plea of *nolo contendere* and was fined \$150.—[*Notice of Judgment No. 6550; issued Dec. 29, 1919.*]

Correspondence

"CREDULITY AND CURES"

To the Editor:—The admirable article of Dr. Frederick Peterson (*THE JOURNAL*, Dec. 6, 1919, p. 1737) is so clearly and entertainingly written and, on the whole, so sane and strong, that a certain error in it might, if not corrected, tend to do much harm by misleading practicing physicians. I refer to the implied condemnation of the prescription of glasses for the remedy of certain reflex nervous disturbances by the relief of eye strain. In his reasoning, the gifted author strangely seems to have fallen into the fallacy termed by logicians "non sequitur."

One might, for example, argue in this fashion:

Freudian psychoanalysis is ill founded and repulsive.
Freudian psychoanalysis is advocated by certain neurologists.
Ergo, all neurologists are untrustworthy.

But it is quite evident that the conclusion does not follow from the premises. The correct conclusion is: Those neurologists who advocate freudian psychoanalysis are mistaken, and not to be followed in that respect.

Concerning eye strain and its relief, Dr. Peterson's syllogism is practically as follows:

Certain ophthalmologists formerly practiced a wrong method (operation) for the relief of muscular imbalance of the eyes.

Another ophthalmologist pointed out a different and correct method (prism exercises) of remedying muscular imbalance, and also called attention to the importance of correct refraction in the relief of reflex disorders provoked by eye strain, and especially of disorder dependent on small degrees of astigmatism.

Ergo, the second ophthalmologist was wrong.

The reality of eye strain as a provocative condition, in certain persons, of many sorts of reflex disturbances, surely cannot be doubted at this period of medical observation. We have all seen migraine, various forms of tic, persistent headache, recurrent vertigo, and gastro-enteric, cardiovascular and nervous disturbances of many kinds relieved for long periods, and sometimes permanently, by the use of lenses prescribed after careful measurement and adjustment to the needs of the particular case. This is an everyday commonplace of medical experience, and needs no elaboration. Neurasthenia—the "fatigue neurosis" of Dercum—is a reality; but many cases are miscalled neurasthenia and the patient vainly submitted to rest cures, in which, later, a

correct diagnosis of eyestrain is followed by relief through correctly measured and properly adjusted lenses. Does this prove that there is no such thing as neurasthenia or no value in rest cures? Not at all. But it does indicate that neither the ophthalmologist nor the neurologist who makes a correct diagnosis can be blamed for his confrères who do not make correct diagnoses.

The same thing may be said concerning hysteria, with this addition: that in certain persons predisposed to hysterical manifestations, unsuspected and uncorrected visual error—commonly hyperopic astigmatism, but not confined to that—will provoke such disturbances; while its relief will tend toward quieting them.

When the history of American medicine comes to be written by an impartial and broad-minded observer, I am quite sure that the names of Weir Mitchell, William Thomson and George M. Gould will be jointly honored for their contributions to this field of diagnosis and therapeutics—Mitchell and Thomson for the discovery and demonstration of the possibilities of eye strain as a provocative of various forms of reflex disorder, and Gould for his enlargement of the field and for the courage with which, in the face of difficulties and discouragements innumerable, he has persisted in preaching the truth. That he has used violent language in his preachments may be admitted and regretted; but I am tempted in this connection to quote the comment of Henry Adams on Lowell's criticism of John Bright:

As the party rose from the table and passed into the drawing room, Adams said to Lowell that Bright was very fine. "Yes!" replied Lowell, "but too violent!"

Precisely this was the point that Adams doubted. Bright knew his Englishmen better than Lowell did—better than England did. He knew what amount of violence in language was necessary to drive an idea into a Lancashire or Yorkshire head. He knew that no violence was enough to affect a Somersetshire or Wiltshire peasant. Bright kept his own head clear and cool. He was not excited; he never betrayed excitement.

Perhaps the future historian may conclude that Gould knew better than the rest of us "just what amount of violence in language was necessary to drive an idea into the [medical] head."

S. SOLIS COHEN, M.D., Philadelphia.

MEDICAL VETERANS OF THE WORLD WAR

To the Editor:—The beginning of this war found the medical profession of the country wholly unprepared for the tremendous military responsibilities which were to be thrown on it. No organization had been perfected by which the profession could be called into service, and no instructions had been given to the profession to acquaint them with the duties of a medical officer in the field with troops.

The Medical Department of the Army had been accumulating for many years field medical supplies, and through the great foresight of Col. Jefferson R. Kean, Medical Corps, the American Red Cross, with which he was serving, had organized a large number of base hospital units from among the staffs of our large and important civil hospitals.

The Medical Reserve Corps had not been developed, and the officers who were in this corps and who were fit for military service had not been instructed in their duties as medical officers. This laid a tremendous task on the Medical Department to meet the emergency when war was declared in April, 1917.

The response the profession made to the emergency was superb. We are all proud of the manner in which the country as a whole met its obligations. And we are all proud of the manner in which special organizations met their obligations. But I am sure it is a fair statement that no part of our country met its call in the superlative manner the medical profession met theirs.

At the beginning of the war there were about 450 officers of the Medical Corps and something like 2,000 officers of the Reserve Corps. Many of the latter were not physically fit for military service, and some were essential to the welfare of their communities. But through the tremendous efforts of all concerned, medical officers were obtained in sufficient numbers to meet the demands as they arose.

The medical men who came into the corps brought with them the finest spirit that ever existed in any organization. It was the spirit of service, which enabled them to meet their new duties in a most admirable way. When the armistice was signed, there were more than 30,000 physicians in active service. This does not include the hundreds of physicians who were assisting the Provost Marshal in executing the draft and in doing other essential work necessary to carry on the great war. These officers have been demobilized just as rapidly as the interests of the service would permit, so that today there are only 1,200 temporary officers remaining.

Americans, as a people, have the very highest ideals regarding the quality of medical and surgical treatment that is due our soldiers, and it is only fair to state that the greatly enlarged Medical Corps was able to meet their ideals in every respect. There were some complaints at the beginning when troops were rushed into camp before adequate provisions could be made to care for the sick; but careful investigations, which were made, revealed the fact that the medical man had met his emergency as well as it was humanly possible to do with the facilities at hand. In France the American soldier was cared for as no other soldier was ever cared for. I think this can be said with perfect fairness, but with the understanding that we started with the advantage of the information our allies had accumulated during their three years of war. The wounded man was treated by the most expert surgeons of this country, and the man who fell ill from disease was cared for by the best internists of the land. The sick and wounded who were brought back to the United States have been treated in the best equipped hospitals this country has ever seen. The number now remaining under treatment in our hospitals is so small that it is almost a negligible quantity.

The effort this country made in meeting the responsibilities of war was the greatest thing that has occurred in our history, and the part the medical profession played has only added another bright page to the traditions of which we are so proud. I am sure every medical officer should be proud of having had an opportunity to play even a very small part in the tremendous effort which has been carried on since April, 1917.

And now that the profession has returned to its duties in civil life, I think it would be a tremendous mistake if we should not band ourselves together in some organization which would perpetuate the traditions of this great war, which would keep us in closer touch in the future, and which would keep alive an organization which would meet any obligations which the profession might be called on in the future to discharge to our government. I know of no better way of carrying on these principles than for all of us to become active members of the Medical Veterans of the World War, an organization composed exclusively of those who served in the Medical Department of the federal government.

M. W. IRELAND, M.D., Washington, D. C.

Surgeon-General, U. S. Army.

Ocular Complications of Vaccination Against Typhoid.

A case of febrile herpes of the cornea developing a few hours after antityphoid vaccination is reported by Dr. F. M. Fernández in his *Revista cubana de oftalmología*, page 592. The issue of the *Revista* containing it is the fourth number of this new quarterly, and has 229 pages and twenty-eight original articles. Dr. R. Pacheco Luna of Guatemala also reports, page 600, a somewhat similar case in which a man of 52 had a relapse of herpes of the cornea after vaccination against typhoid. The first attack had been three years before. Pacheco Luna reviews the literature on the subject, and states that his case proves that herpes of the cornea is not due directly to the typhoid vaccine: in some of the cases on record it was evidently merely a coincidence. He adds that it is better to refrain from the vaccination when there is a history of preceding disease of the uveal tract, especially in the syphilitic, tuberculous, rheumatic, etc. There does not seem to be any ocular lesion which depends solely and exclusively on the typhoid vaccine.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

THE METRIC SYSTEM

To the Editor:—1. What action has the American Medical Association taken regarding the adoption of the metric system both in this country and as a world wide standard of weights and measures? If possible, give me date and place of action taken.

2. What is the procedure for bringing this important subject before our association?

WILLIAM H. QUAY, M.D., Townsville, Pa.

ANSWER.—1. THE JOURNAL, May 18, 1895, p. 766, in the official reports of the proceedings of the forty-sixth annual session, held in Baltimore in 1895, reports:

The General Business Committee endorses the following recommendations from the Section on Materia Medica and Pharmacy:

Resolved, That in view of the adoption of the Metric System in the U. S. Pharmacopeia, this section recommends the more thorough instruction of the students at the medical schools in the use of metric weights and measures, and further recommends that physicians, when writing metric prescriptions, always make use of the signs Grm. and Cc. to distinguish between quantities by weight and volume.

2. New business may be presented in the House of Delegates by any delegate in attendance at a meeting. The ideal procedure for submitting a proposition is to present it first to a component county society that a memorial on the question may be addressed to the constituent state or territorial association. Then, if approved, its delegation will submit the subject to the House of Delegates of the American Medical Association.

BRAZILIAN WORK ON SNAKE VENOMS

To the Editor:—In THE JOURNAL, Aug. 23, 1919, p. 629, in the answer to a query from W. T. P., an injustice is done to Brazilian scientists. The question referred to snake venoms, and the inquirer requested bibliographic information on this subject. The answer mentioned twelve authors, and no mention is made of Brazilian works on this subject. I wish to state that the "ophidism" (as we call it here) is a matter absolutely solved by Brazilian scientists, among whom stands out the name of Dr. Vital Brazil Mineiro da Campanha, the discoverer of the antivenom serums. At present in Brazil, the only ones who die from snake bites are those who wish to do so.

D. DE MORAES LIMA, M.D., Ribeirao Preto, Brazil.

COMMENT.—Our list was a suggestive one and by no means complete. Among South American references might have been included the following from Brazil:

Brazil, Vital: Sobre un novo tratamento organoterapico do ophidismo do Dr. Ernst von Bassewitz, *Rev. med. de S. Paulo* 7:25, 1904; Ophidismo no Brazil, *Brazil-med.* 20:7, 1906; Serum anti-ophidico, *ibid.* 17:384, 1903; Da serumterapia no envenenamento ophidico, *ibid.* 18:21, 31, 1904.

Barroso, S.: Mordeduras de cobra e seu tratamento, Rio de Janeiro, 1889.

Villela, E.: Antiscorpion serotherapy, *Brazil-med.*, May 25, 1918.

Pinto: Campaign Against Snake Poisoning in Brazil, *Brazil-med.*, July 8, 1916.

Effective Treatment of Tuberculosis.—The physician is a life saver who promptly prescribes what may be required to prevent the incipient case of tuberculosis from becoming a plain case.—*Bull. Maine State Dept. of Health*, October, 1919.

KANSAS: Topeka, Feb. 10. Sec., Dr. H. A. Dykes, Lebanon.

NATIONAL BOARD OF MEDICAL EXAMINERS: St. Louis and Chicago, Feb. 18-25. Sec., Dr. J. S. Rodman, 1310 Medical Arts Bldg., Philadelphia, Pa.

NEW YORK: New York City, Albany, Buffalo, Syracuse, Jan. 27-31. Asst. Professional Examinations, Mr. H. J. Hamilton, Albany.

VERMONT: Burlington, Feb. 10-12. Sec., Dr. W. Scott Nay, Underhill.

EFFICIENT HOSPITALS

ASA S. BACON

Superintendent, Presbyterian Hospital

CHICAGO

Hospitals are often compared to hotels; but while they are, in a sense, hotels for the sick, there is a distinct difference between the two from the patient's standpoint. A man goes

to a hotel prepared to pay for his accommodation: he is usually on a business or vacation trip. Sickness comes to a man unexpectedly and catches him unprepared: he is sent to a hospital unprepared: he is not on a business or vacation trip. His salary is often discontinued. If a well man does not like his hotel accommodations, he can go elsewhere; but a sick man entering a hospital has to take what he can get. The man in moderate circumstances, unable to pay for an expensive room, must take a ward bed, which his sensitive condition causes him to rebel against, and the physician wastes a great deal of valuable

time in getting his patient properly located. A patient came to my office the other day to say good-by. He told me about the kind attention he had received from physicians and nurses, but he added, "When I return, put me in a closet rather than in the ward."

Wards are intended for the poor people, for charity patients or for those who can pay but a small amount. Labor conditions have so changed that the average working man does not want charity. The labor leaders frown on it and ask for a sufficient wage to enable the laborer to pay for his care, and they are going to get it. It is now evident that national prohibition is also going to be an important factor in reducing charity work.

When a man is sick, his earning capacity is cut off. He is a nonproducer. It is the duty of the hospital to get him well in the quickest time possible, so that he can get back to work and begin producing.

To provide efficient hospitals to serve the people in moderate circumstances, at charges within their means, giving

Fig. 1.—Typical room in perspective.

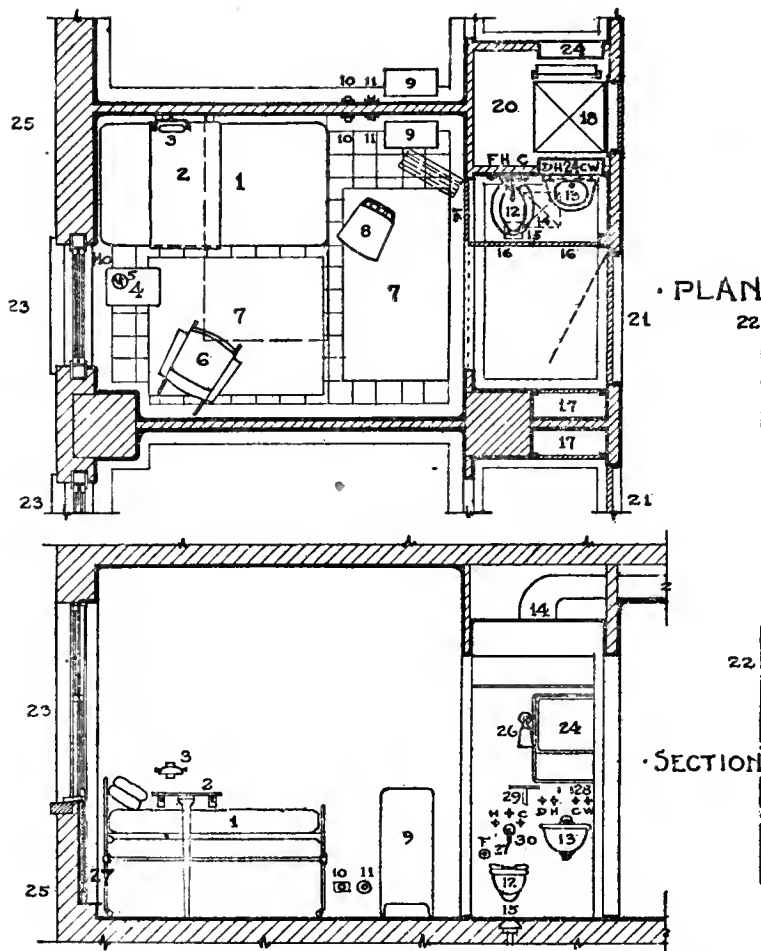

Fig. 2.—Plan and section of typical room: 1, standard bed and back rest; 2, adjustable table (removable); 3, reading lamp (removable); 4, nursing table; 5, telephone; 6, rocking chair; 7, small rug; 8, straight-back chair; 9, radiator; 10, base plugs; 11, vacuum outlets; 12, water closet; 13, lavatory; 14, exhaust vent register; 15, floor drain; 16, three-leaf door; 17, lockers; 18, dumbwaiters; 19, door to dumbwaiter; 20, pipe space; 21, entrance to rooms; 22, center line of corridor; 23, windows; 24, steel cabinet for equipment; 25, exterior wall; 26, electric light and attachment; 27, sliding screen; 28, staple ringer hooks; 29, shelf for equipment work; 30, swivel spout for bedpan and washing and shower attachment; B, hot water; C, cold water; D, drinking water; W, waste; F, flushing valve. These and the accompanying plans were made by Berlin, Swern and Randall, architects and engineers, 19 South La Salle Street, Chicago.

them all the conveniences of the most exclusive institutions, and rendering the much needed educational work to the community, is the ideal to be attained; but to accomplish this ideal requires new methods and much thought.

Present hospitals are rated at a certain bed capacity, but it seldom happens that the maximum capacity is reached when there are wards. This is due to the constant variation in the percentages of the various cases handled, namely, the proportion of calls for men's or women's beds does not remain the same, and certain diseases seem to come in epidemics. This makes imperative some scheme for flexibility in the use of beds. The private room for each patient, with its complete utility equipment, not only provides comfort, but absolutely solves this problem. The question of contagion is eliminated, each room is complete in itself, needing no service which is common to any other; nor does a patient, developing some contagious disease at a late date, have to be moved at possibly the most critical period of his illness because of danger to others. Again, the room temperature can be kept at the degree best suited to each patient, or the room can be turned into a

solarium if desired. Better examinations can be made and better histories taken than in a ward. They may be made at odd hours, which if done in a ward might disturb others. Hospital visiting rules can also be regulated to fit the individual patient and need not be allowed to fret the patient for the sake of observing a rule. It also allows the occupancy of *all the beds all of the time*.

In working out this plan, certain fundamental principles of construction and organization have been found to be imperative. These are the abandonment of wards and the substitution of small private rooms; the elimination of special duty rooms and general lavatories, and the substitution of a toilet and lavatory in each patient's room; the abandonment of floor diet kitchens and serving rooms, and the substitution of one large central kitchen and serving station; the abandonment of floor linen rooms, and the substitution of one central linen supply room; the abandonment of long corridors necessitating the carrying for long distances of food, linen, drugs and supplies, and the substitution of dumb waiters direct from the central supply rooms to each floor section; and the installation of pneumatic tubes to carry written requisitions from each floor to the central supply station, and also to carry any supplies that can enter the tube.

Probably the most trying question to every superintendent is the conservation of supplies. There are more provisions used than the capacity warrants, and there is an enormous shrinkage in the linens and household goods. Where do they go? Even the best supervision cannot control this, and numerous rules and regulations are hard to enforce. A trip through any large, progressive factory will show clearly that the materials and tools are not spread out at random, and that when the day's work is done every article is in its place. This is an application of efficient methods. Why not apply them to the hospital? In the new plan, the amount of provisions and equipment required will be reduced by the elimination of cooking and the necessary paraphernalia throughout the build-

Fig. 3.—Typical floor plan of 160 bed hospital: 1, elevator lobby; 2, elevators; 3, service dumbwaiters; 4, specimen dumbwaiters; 5, linen and waste paper chute; 6, vent ducts; 7, pipe shaft; 8, medicine cabinet; 9, stairways; 10, service and janitor room; 11, toilet room; 12, dressing room; 13, bath and toilet rooms; 14, shower and tub room; 15, floor drain; 16, three-leaf door; 17, lockers; 18, dumbwaiters; 19, door to dumbwaiter; 20, pipe space; 21, entrance to rooms; 22, center line of corridor; 23, windows; 24, steel cabinet for equipment; 25, exterior wall; 26, electric light and attachment; 27, sliding screen; 28, staple ringer hooks; 29, shelf for equipment work; 30, swivel spout for bedpan and washing and shower attachment. According to this plan a five story building would have a capacity of 120 beds, a six story building 160, and a seven story building 200 beds.

Fig. 4.—First floor plan of thirty bed hospital: 1, general rotunda, from the center of which a view of every door is secured; 2, service dumbwaiters from basement; 3, chart room, library and depository for histories; 4, laboratory and drug room; 5, men's toilet and locker room; 6, women's toilet and locker room; 7, general waiting room; 8, office of superintendent; 9, examining room and emergency operating room; 10, major operating room; 11, sterilizing and instrument room; 12, roentgen-ray room and dark room; 13, main entrance; 14, rear and ambulance entrance; 15, storage, chairs, carts, etc.; 16, special room with bath; 17, special bath; 18, typical room; 19, special room with bath.

ing and the centralization of it in one general kitchen. The centralization of serving eliminates poor judgment on the part of floor nurses in setting up trays, and the use of unnecessary dishes, and provides a means of checking up more systematically those that are used. The cooking also is more economically done in bulk and is under the supervision of an expert dietitian. The elimination of linen and supply rooms all over the building, and the collecting together of all household supplies in one general storeroom, allow absolute supervision, as in a toolroom in a factory. In this way, carelessness and extravagance can be located. *Centralized control is the system which we should establish in efficient hospitals.*

If more people went to the hospital when they were sick, it would be possible to collect more data in regard to the various diseases. Hospital treatment in the past has been considered a luxury, and has been resorted to only when every other means of care failed. This should be reversed, and would be, if the charges for hospital services were within reach of the general public. The efficient city or community hospital, floor plans for which are submitted herewith, makes this possible. It will collect the cases of sickness in a community, tabulate them, and file their histories for future reference. It takes sickness out of the home and from the hands of inexperienced

care and puts it under the proper supervision, giving it the advantage of trained nursing. Epidemics and the spreading of disease in homes can at once be controlled. Physicians will be able to give more of their time to their profession and less to traveling around from house to house. They can compare notes and gain from each other's experiences, to the advantage of the community as a whole.

Thousands of small hospitals are going to be erected. Efficiency and economy in the medical as well as the material service of the hospital should be our standard.

ILLUSTRATIVE PLANS

Figure 1 is an interior diagram perspective of the small typical room and shows the equipment in its place.

Figure 2 illustrates the small typical room in direct plan and section elevation. The intention of this drawing is to show the compactness of the facilities and the arrangement for furniture. This is the minimum size for the room advisable. This can be expanded and made more commodious as the building funds will allow, without interfering with the practicability of the idea.

Figure 3 is a suggested floor plan for a building of from 120 to 200 beds. The ground floor of such a building would be devoted to service, first floor to administration, physicians' offices, receiving departments and dispensary, and the top floor, operating, roentgen-ray and laboratory department. The use of the U-shaped plan allows the strategic placing of dumbwaiters around the central kitchen on the service floor. These dumbwaiters and elevators are the arteries of communication between all of the departments in the building.

Figure 4 is a suggested layout for a small community hospital of about thirty bed capacity.

Fig. 5.—Second floor plan of eighty-five bed hospital: 1, general rotunda; 2, service dumbwaiters; 3, elevator and stair halls; 4, elevator; 5, sick babies' room; 6, milk laboratory; 7, work room; 8, nursery; 9, toilet room; 10, work room; 11, delivery room; 12, wheel chairs and carts; 13, solariums; 14, bath room for babies; 15, dressing room for children; 16, typical room; 17, double room and utilities; 18, bath room for babies; 19, dressing room for children.

using the individual room idea. All of the departments with which the patients come in contact are located on this floor, together with the general nursing. All of the service departments are collected together in the ground floor, where proper supervision can be given, with dumbwaiters as the arteries of communication between the two floors.

Figure 5 is a suggested layout similar to the one in Figure 4, for a community hospital of approximately eighty-five beds. Here again the departments with which the patients come in contact are collected together on the upper floors, and the ground floor is devoted entirely to service, with the dumbwaiters and elevators as arteries of communication. The operating suite, roentgen-ray department and laboratories of this particular scheme are located on the top floor, and administration on the first floor, together with a dispensary and physicians' offices if required.

Miscellany

PHYSICIANS' LIABILITY FOR INCOME TAX

The first of the year brings up again the annual question, "How much income tax must I pay for 1919?" In case of salaried officials, business men whose operating expenses are distinctly separate from their personal and family expenses, and those happy persons who derive a fixed and definite income from investments, this question is easily answered. The difficulty which has arisen in applying the income tax law to physicians is one that is inherent in the practice of medicine and for which the old habit of physicians of lumping their personal and professional expenses is responsible. It is, or was before the passage of the federal income tax law, difficult to determine what constitutes the actual income of physicians. More than any other class of professional men, they have, as a rule, confused gross and net income and have regarded the gross intake for the year as their professional income without regard to the cost of carrying on their business. Owing to the close relation between professional, personal and family habits, no clear dividing line has heretofore been drawn between personal and family expenses and the expenses of carrying on the practice. As a result, few physicians have kept sufficiently accurate records to enable them to separate these two classes of expenditures. In the first year or two of operation of the federal income tax law, many physicians paid a tax on a larger income than they were really liable for, owing to the fact that they did not understand what were legitimate exemptions under the law. Since the passage of the law, a number of rulings have been issued defining the meaning of the law, especially as it refers to physicians.

There are two general principles underlying the application of the federal income tax law: The first is that a man's income is the difference between his gross intake for the year and the total cost of carrying on his business. The second is that all money paid out for expenses directly connected with one's business and for articles the use of which is limited to the current year is deductible, but that money paid out for articles which will be used over a considerable period of time is not expense but investment, and as such is not deductible. For instance, the original cost of an automobile is an investment and not an expense; but the annual depreciation or loss of value of an automobile used by a physician for professional purposes is a legitimate and deductible expense. As the average automobile is estimated to have a life period of five years, a deduction of 20 per cent. each year on the original cost of the automobile is allowed. In the same way, office furniture and equipment is not an expense but an investment. Such equipment, however, deteriorates with use and age. A physician is, therefore, allowed to deduct the original cost of the equipment divided by the number of years for which it can be used.

Applying these principles to a physician's income, it is evident that his gross annual income is the total amount of

his actual collections for professional services plus any additional income from any other sources. From this he is allowed to deduct all actual expenses necessary for carrying on his business. This would include office rent and maintenance, such as heat, light, cleaning, attendance, etc., office telephone, salary of a stenographer or office assistant, and the cost of any drugs, dressings or other materials that are used in the treatment or care of patients. But while drugs and dressings are deductible, surgical instruments and appliances are not, since they are for permanent use and are an investment. Depreciation of such instruments or equipment through breakage, wear and tear or use can be deducted, dividing the original cost of the instrument by the number of years of usefulness. Books are an investment, but medical libraries are subject to deterioration. Medical books do not wear out, but they do become old and obsolete. Some books, such as textbooks on anatomy, are good for a lifetime; while books on the practice of medicine and especially on some of the more recent special subjects soon become out of date. The average life of a physician's library can fairly be estimated at twenty years, so that one twentieth of the cost of books during the year can be deducted. Medical journals, being of temporary value, are an expense and not an investment, and consequently subscriptions to medical journals can be deducted. Membership in medical societies of a strictly professional nature is also an expense, and the dues can be deducted; but membership in organizations, whether medical or otherwise, of a social nature, such as physicians' clubs, is a personal expense and is not deductible. Regarding an automobile, as stated above, the original cost is an investment; but one fifth of the cost may be deducted for depreciation. If the automobile is used solely for professional purposes, then the upkeep and expense of operation, including gasoline, oil, tire repairs, chauffeur's wages, garage expenses, etc., are deductible. If the automobile is used partly for professional and partly for personal use, then both the depreciation and the expenses should be prorated. Regarding home expenses, if a physician maintains an office in a rented house, then a portion of his house rent can be deducted; but if a physician owns his own home, he is not allowed to make any deduction for rent for his office, whether he uses his home as a place of business or not. He would, of course, be allowed to charge off a proportional amount of the expense of heat, light, telephone, etc. Railway fare and cost of berth, in attending medical society meetings of a strictly professional character may be deducted, but not hotel bills, meals or incidental expenses, the assumption being that these expenses would be incurred whether the physician attended the meeting or remained at home. If the physician uses horses instead of an automobile, the cost of maintenance may be deducted, provided the horses are used entirely for professional purposes; otherwise, the proportionate amount. Depreciation to the proper amount can also be charged off on horses, buggies or sleighs used for professional purposes. Physicians maintaining a laboratory can, of course, deduct the salary or wages of a laboratory assistant, the cost of chemicals, drugs and other materials used, and the depreciation on the laboratory equipment. Physicians maintaining roentgen-ray apparatus or laboratories can deduct salaries paid to operators and depreciation on the cost of equipment. Roentgen tubes and plates which are constantly breaking and have to be replaced would come under the same head as drugs, bandages, etc., and may be deducted. In the case of oculists furnishing glasses to patients, there should be two distinct charges recorded, one for professional services as an oculist and the other for glasses supplied to the patient as merchandise. Contributions to philanthropic, benevolent, religious and humane organizations may be deducted up to 15 per cent. of the total income, but not dues to clubs and social organizations.

The federal income tax law has been productive of two benefits to physicians. The first is that it has compelled physicians to keep more accurate and minute financial records. The second is that it has made it possible for physicians to determine their real income from professional work. Prior to the passage of this law, many physicians were accustomed to regard their total annual-cash receipts as their income.

whereas their actual income was often only a third or a fourth of what they supposed it to be. While it has been a shock to many a man to find that instead of making ten thousand dollars a year, he was really clearing only from five to seven thousand, the result in the end will be highly salutary both to the individual and to the profession.

FEDERAL AID IN THE PROTECTION OF INFANCY AND MATERNITY

Every year about 16,000 mothers die in childbirth and nearly a quarter of a million babies die under one year of age. Most of these deaths are preventable. Among sixteen important countries, thirteen show a more favorable maternal death rate than the United States and six a more favorable infant mortality rate. Maternal mortality and infant mortality from maternal causes are not decreasing in the United States. About one half of all infant deaths occur within six weeks of birth and these early deaths are due chiefly to the condition of the mother and the lack of proper care and instruction for the mother during pregnancy and confinement. Maternal deaths and infant deaths from maternal causes are not decreasing because mothers do not yet have the skilled care and advice that they need. The Children's Bureau has secured detailed information about the mothers of 2,978 babies born within a short preceding period in eight rural areas representing six states. In these confinements, only five women received prenatal care approaching the minimum standard of "adequate" care outlined by the conference on child welfare standards at Washington in May, 1919, and in 80 per cent. of the cases, the mothers reported having had no prenatal care whatever.

BOTULISM FROM EATING CANNED OLIVES

Armstrong, Story and Scott (*Pub. Health Rep.* 34:2877 [Dec. 19] 1919) report on the epidemic of botulism in Canton, Ohio—mentioned in *THE JOURNAL*, Nov. 15, 1919, p. 1538—following a club banquet, Aug. 23, 1919, at which about 200 people were present. The cases were confined to the chef, waiters and diners of one table at which ripe olives, nuts and candy had been substituted for regular items of the menu. By a process of exclusion, graphically portrayed in a tabulation, the attacks were attributed to the ripe olives. Seventeen persons ate or tasted of the olives; fourteen became definitely ill, seven cases ending fatally; three showed no definite symptoms. None were ill who did not partake of the olives. Those who ate the most olives died first, while among those who recovered, the severity of illness bore a close relation to the numbers eaten; three who developed no symptoms ate the least of all. Two diners, who took a relatively large amount and recovered, had partaken freely of alcohol during the evening. The olives were packed in a sealed glass jar, but the vacuum had been accidentally destroyed. They were placed in three table dishes; the contents of two dishes were washed under the tap and drained, the third dish was unwashed. This factor, in the opinion of the authors, may explain the death of one person who ate half an olive, while another recovered after eating two olives. The symptoms were very similar in all cases, varying mainly in severity: headache, diplopia, dimness of vision, and slight vertigo were the most common phenomena. The authors believe that certain diagnostic pitfalls are present in all cases. Botulism may be mistaken for poisoning by mushrooms, wood and ethyl alcohols, cerebral hemorrhage or syphilis, and hysteria; only the occurrence of attacks in others will make the matter clear.

A thorough chemical and biologic investigation of the toxin was made. Chemical examination for definite poisons yielded negative results. Subcutaneous injection of 0.5 c.c. of an emulsion of the suspected fruit in sterile saline solution produced symptoms; 1 c.c. proved lethal to guinea-pigs weighing from 250 to 300 gm.; while from 0.001 c.c. to 1 c.c. of the brine caused death in from eighteen hours to four days. Ingestion of small quantities of brine and of the olives also proved fatal. The brine, after passing through a Berke-

field filter, although culturally sterile, proved highly poisonous on subcutaneous injection; heating at 80 C. for thirty minutes rendered the filtrate harmless.

Anaerobic culture at 37 C. in beef infusion glucose agar yielded a growth of a gas producing, agar fragmenting bacillus, gram positive, motile, coarse, sporogenic, and staining well but irregularly with ordinary dyes. Cultural characteristics and toxin formation led to its identification as a strain of *Bacillus botulinus*. The organism grew well in the brine of unspoiled olives of the same brand, and its spores resisted 100 C. for thirty minutes. Potent toxins developed, a sterile filtrate from a nine-day culture proving lethal in doses of 0.00005 c.c. intraperitoneally. Subcutaneous or intraperitoneal injection of various doses of toxin diluted to 1 c.c. with sterile saline, mixed with 0.5 c.c. of 95 per cent. alcohol, protected guinea-pigs against twenty times the lethal dose. Tests for agglutinins and antitoxins were negative.

Medicolegal

Value After Death of Good Will of Business of Roentgenologist—of Physician

(*In re Caldwell's Estate* (N. Y.), 176 N. Y. Supp. 425)

The Surrogate's Court of New York County holds that, where a physician, who had specialized in roentgenology or the taking of roentgenograms as an aid to physicians, bequeathed the good will of his business, together with the apparatus used in connection therewith, to his two assistants, one of whom was a physician who leased the office that had been occupied by the testator, but removed the latter's name from the door and substituted his own, the transfer tax appraiser erred in valuing the good will at \$38,874.12, and that his report should be remitted to him for the purpose of excluding the good will as an element of value. The court says that the question of whether the good will of the practice and business of a man who has attained eminence in his profession has, on his death, a value that is capable of ascertainment or computation, does not seem to have been decided in the reported cases. The extensive and lucrative business transacted by the decedent was the result of his reputation for great skill in taking roentgenograms, and as this skill and knowledge died with him it could not constitute an element of good will that would survive him. The death of a man who had attained such prominence and reputation as a roentgenologist must have received such publicity as would bring it to the attention of practically all the members of the medical profession who knew him by reputation or who would ordinarily have sent patients to him. Therefore, after his death those physicians would not send any more patients to the office theretofore conducted by him; and if the office passed into the possession of another physician or roentgenologist, it could scarcely be said that its former occupancy by the decedent made it more valuable to his successor. The skill and knowledge which the physician who had been an assistant to the decedent acquired during his association with the decedent, and which induced physicians to send their patients to him, were entirely personal to him, and were not transferred to him by the decedent as part of the good will of the business. The reputation which the decedent had acquired was personal to him, and it was not due to the place where he maintained his office or to any trade mark or trade name.

It has been held that a physician may sell the good will of his business and that the courts will recognize the right of the purchaser to such good will. But there seems to be a distinction between the business sold by a physician during his lifetime and the value of that business after death. If sold by the physician during his lifetime, he could introduce the purchaser to his patients and friends as a prudent and reliable physician, and such introduction would immediately give the purchaser a reputation and standing which otherwise might require years to establish. It seems to the court that such introduction and recommendation to patients con-

stitute the real consideration for the money paid to a retiring professional man by one who wishes to succeed him. But after a man who has acquired a reputation for great skill or knowledge is dead, persons who would go to his office for the purpose of consulting him and availing themselves of his superior skill would not go there merely because the office was still open and occupied by another person, who had no reputation for superior knowledge or skill.

It seems to the court that the criterion by which it may be determined whether the business of the decedent had a good will capable of being transferred by his will is: If an inconspicuous and unknown physician should take the office which had been occupied by the decedent at the time of his death, and put his own name on the door, would the clients of the decedent, or a considerable number of them, continue to send their patients to that office? In the court's opinion, it is extremely improbable that such a person would receive any patients from the physicians who patronized the decedent because of his exceptional skill and knowledge.

Liability of Operating Surgeons to Pay Assistants

(*Seemple v. Ringo* (N. D.), 172 N. W. R. 817)

The Supreme Court of North Dakota, in reversing a judgment rendered on a verdict directed in favor of the defendant, and ordering a new trial, holds that in surgery the proper administration of an anesthetic is an essential part of the operation, for which a surgeon is commonly paid a good round fee, which includes the minor fee of an assistant. When he employs an assistant, the presumption is that he agrees to pay him, unless the contrary appears from express words or conditions.

In the opinion in the case, prepared by Justice Robinson, it is said that the complaint averred that on several occasions, at the special request of the defendant, the plaintiff administered anesthetics to patients of the defendant on whom the latter performed surgical operations; that the plaintiff's services were reasonably worth \$25, which the defendant promised to pay. The defendant admitted that at his request the plaintiff performed such services, and that these were reasonably worth \$25, but set up the defense that in requesting the services he acted merely as the agent of his patients, and did not assume any personal obligation, and that in such cases it is customary for a physician to administer anesthetics and to look for his pay to the patients, and not to the surgeon calling him. In this case the defendant had a hospital, and did quite an extensive operating business. On the several occasions, without disclosing the names of his patients or anything concerning them, he requested and accepted the services of the plaintiff in what are known as minor and major surgical operations. In such a case the principal surgeon commonly gets a good liberal fee for doing everything necessary for a successful operation. In modern surgery the proper administration of an anesthetic is a very essential part of the operation. It may also be necessary to obtain from a druggist antiseptic gauze or cotton and other small things. All such services and necessities are properly chargeable to the surgeon when he orders them without giving the name of his patient as the person to whom the charge should be made. In this case it appeared that, at the request of the defendant, the plaintiff went and administered anesthetics, not knowing anything of the patients, not even their names, and not looking to them for payment. It also appeared from abundant evidence that the custom is for a surgeon to pay the small fee of an assistant physician whom he clearly requests to administer an anesthetic. Clearly both the presumption of law and the weight of the testimony was in favor of the plaintiff. The case should have been submitted to the jury. Justice Birdzell concurs; Justices Bronson and Grace concur in the result; and Chief Justice Christianson dissents.

Chief Justice Christianson says, in his dissenting opinion, that the plaintiff testified that in the first case in which he helped the defendant they were in the Elks' Home and the defendant asked him if he would care to go out for a drive with him to see a case of gunshot wound of the knee; it was another physician's case, and that physician wanted to assist

the defendant in the operation, and they had the plaintiff give the anesthetic. In the next case the defendant telephoned to the plaintiff's office and asked him if he could go up and give an anesthetic. The third case was one wherein the defendant called the plaintiff to give an anesthetic for a patient on whom he was operating for appendicitis. The next case was one in which the defendant asked him if he would come over and see a case with him. It was undisputed that the defendant at no time expressly promised to pay the plaintiff for the services which he rendered, and the sole question was whether, on the facts stated, there was an implied promise on the part of the defendant to pay for such services. The plaintiff knew that the defendant had been engaged as attending physician by certain patients. The defendant summoned the plaintiff to assist in treating such patients. The plaintiff met them. They received the benefit of his services. They were all persons of mature age, and in possession of their faculties. It would seem that under these circumstances the law did not imply any promise on the part of the defendant to pay the plaintiff for the services which he performed. In order to be binding, a custom must be certain, uniform and general, which the plaintiff's evidence did not show of the alleged custom for surgeons to pay assistant physicians.

Release Not Bar to Action for Roentgen-Ray Burns

(*Wheat et al. v. Carter* (N. H.), 106 Atl. R. 602)

The Supreme Court of New Hampshire, in overruling exceptions to a judgment that dismissed the plaintiff's petition for an injunction to prevent the defendant from prosecuting an action which he had brought against them because they had burned him with a roentgen-ray machine after he had employed them to treat his hand which had been injured, holds that a release which he gave to his employers, in whose service he was injured, was not necessarily a bar to his right of action against the plaintiffs. The court says that it is settled in New Hampshire that the release of one joint tort-feasor or wrong-doer is a bar to a suit against the others; and that is also true as to the effect of a release when the releasor's loss is caused by the concurrent misconduct of the one released and others. The reason that a settlement with one of several tort-feasors or wrong-doers is ever a bar to a suit against the others is that the injured party has been fully compensated for the loss which he is seeking to recover in the second suit. Since this is so, the question in this case was whether the defendant had already been compensated for the loss he sustained as the result of the plaintiffs' use of the roentgen-ray machine, not, as the plaintiffs contended, whether his employers might have been liable for that loss. In other words, the test to determine whether the release was a bar to his suit against the plaintiffs was to inquire as to the extent of the claim he made at the time he settled with his employers. Was he claiming to recover all the loss he sustained as the result of the original injury to his hand, or only the loss which resulted immediately from that injury? However the fact may be in other states, in New Hampshire the issue raised by that inquiry was an issue of fact to be determined, like all such issues, by the weight of competent evidence. The question, therefore, which was raised by the plaintiff's exception to the sufficiency of the evidence, was whether it would warrant a finding that the defendant had not been compensated for the loss he was seeking to recover from the plaintiffs. It was permissible, when considering that issue, to consider the defendant's testimony, even though it might contradict the terms of the release. In short, notwithstanding his employers might have been liable for all the loss the defendant sustained, and the release included all claims he might have against them, it was permissible for him in this proceeding to show just what he was claiming when he settled with them, for these plaintiffs were not parties to the release. In other words, the release in and of itself was not a bar to the defendant's suit against the plaintiffs; but, if he had already been compensated by his employers for the loss he was seeking to recover in that suit, that fact was a bar to the suit.

Society Proceedings

WESTERN SURGICAL ASSOCIATION

Twenty-Ninth Annual Meeting, held in Kansas City, Mo., Dec. 5-6, 1919

The President, DR. ROLAND HILL, St. Louis, in the Chair

Artificial Impaction of Femur in Aged

DR. CHARLES D. LOCKWOOD, Pasadena, Calif.: Artificial impaction affords immediate bony contact and insures an adequate blood supply for union. With the patient under anesthesia, the limb is placed in extreme abduction and strong traction, with slight internal rotation. The great trochanter, protected by two layers of felt, is struck three or four swinging blows with a large wooden mallet. A light plaster-of-Paris cast is applied extending from below the knee to the waist line and including the sound limb to the knee. The anesthesia lasts only five or ten minutes, and there is no shock to the patient. The patient is placed on a fracture bed equipped with a special frame and elevating device, enabling the nurse to raise the patient with ease, to bathe, attend to the bowels, and to change the bedding. The cast may be removed as early as the eighth week; but if well borne, it should be left on for twelve weeks. By the end of the fourth month the patient is up and about on crutches, and is bearing some weight on the broken leg. I have treated three patients more than 70 years of age by this method, and all are walking and perfectly well.

Tuberculosis of Joints; Rollier's Heliotherapy

DR. GUSTAV SCHWYZER, Minneapolis: It is my practice to operate in every case of tuberculous joint whenever it is feasible, with Esmarch's constrictor applied. Only with this bloodless procedure is it possible to differentiate between healthy and diseased tissues. In operating, I generally follow the method of Kocher. It would be taking another great step ahead in the treatment of surgical tuberculosis if we could establish numerous institutions in America where Rollier's treatment could be used intelligently; but there will always be persons who cannot spend from one year to three years in such institutions, waiting for a definite cure. For these patients, surgery may be preferable.

A Mixture of Ethyl Chlorid, Chloroform and Ether for

General Anesthesia: An Experience in War Surgery

DR. E. P. QUAIN, Bismarck, N. D.: In France this mixture was considered the most suitable anesthetic for most minor injuries as well as for wounds of moderate severity. We employed it as the anesthetic of choice for most operations that could be finished within fifteen or twenty minutes. In many instances, therefore, the speed of the operating team was the criterion as to whether the choice would be the ethyl chlorid mixture or simply ether. We used ethyl chlorid, 5 c.c.; chloroform, 1 c.c., and ether, 24 c.c. This mixture is poured on a piece of flannel, which is spread out smoothly over a similar piece of flannel laid on the patient's face. A mask is placed over the face so that the margin of the mask is held firmly around the face, under the chin, in front of the ears and over the top of the head. The mask should be as air-tight as possible. There can be no reason why this mixture should not be used in emergency surgery in civil practice when conditions and necessities correspond more or less to those of the wounded soldiers.

Operative Technic in Spina Bifida

This paper, by Dr. Joseph Rihus Eastman, Indianapolis, will be published in full in THE JOURNAL.

Rhinophyma

DR. M. G. SEELIG, St. Louis: The treatment of the disease is exclusively operative. The most satisfactory operative procedure consists in shaving off the redundant tissue until the nose is brought back to what is believed to have been its original form. In this shaving process, two things should be borne in mind: 1. One should not shave too deeply. 2. A thin rim of epithelium should be preserved around the nares. If the shaving is carried too deeply, all sebaceous gland rests

are removed, and there are left no niduses of epithelium from which, as brood centers, epithelization may spread. This delays healing, and even if the nose be grafted, the resultant skin has a harsh, white, dry appearance so striking as always to command attention and cause comment. Furthermore, deep shaving may injure the nasal cartilages and set up a stubborn perichondritis. If a thin ring of intact skin is not left around the nares, serious disfigurement may result from the contractions incident to cicatrization. Hemorrhage, which is usually very free, is checked with comparative ease by simple gauze pressure, and the patient is sent to bed with a large gauze pad well smeared with petrolatum over the nose. Next day this pad is removed, and the denuded area strapped with imbricated strips of sterile zinc oxid adhesive plaster. This dressing is changed daily. Skin grafting is not necessary.

Diaphragmatic Hernia

DR. T. F. RIGGS, Pierre, S. D.: According to the authorities, the great majority of diaphragmatic hernias occur to the left of the midline. My case was one of true traumatic hernia on the right of the median line.

Jaundice and Its Surgical Significance

DR. CHARLES H. MAYO, Rochester, Minn.: In approximately 50 per cent. of cases, the jaundice is caused by obstruction of the common duct by gallstones; in 20 per cent. it is caused by absorption of bile in the liver, or infective or catarrhal jaundice without duct obstruction. From 5 to 8 per cent. of cases of jaundice are caused by serious infection of the gallbladder, possibly gangrene with or without stones. Jaundice from cancer represents 15 per cent. of the cases seen; one half of these cases are caused by cancer of the liver, and the other half, by cancer of the pancreas or the gallbladder and ducts. Jaundice is a late symptom of gallstones in the majority of cases, the result of neglect to recognize the condition or to advise operation in the preventive period. The mortality following cholecystectomy for cholecystitis, with or without stones, is low: only 1.8 per cent. In 2,460 operations performed during a period of three years. There were 337 cases in which both cholecystectomy and choledochotomy were done, with a mortality of 3.2 per cent. In a very serious group of thirty-six cases of obstruction and malignancy, cholecystectomy and choledochotomy were done, with a mortality of 16.6 per cent. Choledochotomy alone was done in a somewhat similar group of forty-seven cases, with a mortality of 15 per cent. If all the choledochotomies are grouped together, however, the mortality in 420 cases is 5.7 per cent., too high a mortality for simple cases of stone and obstruction, and too low for the late and complicated cases, including the cancer cases. Stones were found in the common duct in 274 of the 420 cases.

Congenital Anomaly of Duodenum and Its Surgical Significance

DR. LEONARD FREEMAN, Denver: I have operated in six cases of duodenal obstruction. In none was the diagnosis made previous to the operation. Partial occlusion of the duodenum at the duodenojejunal angle, simulating pyloric obstruction, occasionally occurs from the persistence of a condition normally existing in fetal life. The duodenum, instead of appearing in the abdominal cavity from beneath the transverse megacolon to the left of the spine, emerges to the right, its transverse and ascending portions possessing a peritoneal covering and mesentery of their own, similar to the rest of the small intestine, instead of being fixed in fibrous tissue, as is normally the case. At the duodenojejunal angle, however, the bowel is hung up to the root of the colonic mesentery by a firm adhesion, the kink thus produced being intensified by the downward pull of the free duodenal loop. This kink is deeply situated, and in freeing it care must be taken not to injure the bowel, the inferior mesenteric veins or the left colic artery. A considerable denudation of the intestine may be necessary, which should be covered either by reuniting the peritoneum or by means of a free omental graft.

Surgical Treatment of Empyema

DR. W. W. GRANT, Denver: In the fall of 1917 and the spring of 1918, I operated in twenty-eight cases of empyema,

with a mortality of six cases. In the winter of 1918 and early in 1919, I operated in three cases with no mortality. In all cases, twenty minutes before the operation, one ounce of whisky was administered, and a hypodermic injection of $\frac{1}{4}$ grain of morphin, $\frac{1}{200}$ grain of atropin and $\frac{1}{2}$ grain of spartein. From 1 to $1\frac{1}{2}$ inches of rib were resected. On the right side, the eighth rib, and on the left side, the ninth or tenth rib, usually in the posterior axillary line, were selected, the aim being to secure the most dependent drainage. A rubber drainage tube, sometimes double, was immediately introduced, and the tissues were sutured snugly around it, the tube was fixed primarily with a suture and a safety pin, and the long outer tube was dropped into a bottle of water beneath the bed as in certain cases of gallbladder drainage. The quantity of pus evacuated varied from 2 to 4 quarts. The discharge diminished rapidly, and on the second or third day the patients were taken to the dressing room twice daily and the cavity irrigated with a 5 per cent. sodium bicarbonate solution, boric acid being added, followed immediately by a solution of iodine. The shortest period in which any patient returned to duty after operation was seventeen days, while the convalescent period in most instances was from two to three months.

Malignant and Benign Tumors of Breast

DR. BYRON B. DAVIS, Omaha: My study of 210 private cases is encouraging rather than discouraging. Operations for cancer save lives. The very early operation, so early that the microscope is necessary to make the diagnosis, is bound to produce better results than the operation done after the disease is easily diagnosed. The radical operation should be directed in such a way as to remove as thoroughly as possible the highways along which the disease is disseminated. The campaign of education of the public with reference to the signs of early cancer and its curability, when operation is performed early, should be continued and kept up unceasingly. The fact should be appreciated that every woman operated on for cancer of the breast, who remains free of the disease, is more powerful propaganda in the community in which she lives than all the tracts that could be written.

Botulism.—The experiments reported on by Dickson and his associates were undertaken to determine the thermal death point of *B. botulinus* and its spores under various conditions. They found that the spores of *B. botulinus*, when mixed with animal or vegetable protein, are much more resistant to heat than has been believed. The acidification of the culture medium by the addition of 5 per cent. lemon juice does not prevent the growth of *B. botulinus* or the formation of its toxin, but the thermal death point of spores of *B. botulinus* is markedly lowered when they are heated in

an acid medium of similar concentration. The addition of cane sugar to beef broth in concentration up to 64 per cent. does not prevent the growth of *B. botulinus* or the formation of its toxin, although it does inhibit both to a certain extent. Certain fruits which have been canned in sugar form suitable mediums for the growth of *B. botulinus* and the development of its toxin. Peaches, apricots and pears were tested. Certain of the methods of canning are inefficient if the raw material happens to be contaminated with spores of *B. botulinus*. This is true of commercial canners' processes as well as of the home canning processes.

Pneumococcus Carriers.—The results of the disinfection experiments made by Sailer and others in their study of pneumococcus carriers may be summarized as follows: Dichloramin-T, dissolved in eucalyptol gave good results; used in solution in chlorosane the results were far less satisfactory. Chlorin gas is not efficient and caused discomfort and is possibly dangerous even in such concentration as was used. Phenol showed good results. The solution in oil is more efficacious than that in glycerin. The use of instillations rather than sprays is perhaps preferable on account of reduced danger of ear infection. Iodin in oil gave good results. It caused no discomfort. Quinin sulphate proved of no value. An accidental observation suggests that it may be valuable in another way. The experiment was under way when the spring epidemic of influenza visited the camp. The carriers of other groups were attacked by the disease in the same proportion as the men of the rest of the camp. No cases of the disease developed in the group being sprayed with the quinin. The prompt subsidence of the epidemic prevented further observations. Chloramin-T is apparently of little value. Carriers were detected by means of smears from the nasopharynx spread on blood agar plates and transplantation of the green pneumococcus colonies in the blood broth medium of Avery. The application of this method to 700 men showed the presence of 16 per cent. of pneumococcus carriers. The authors believe that the contacts of cases of pneumonia should be subjected to culture in the same way as is now done for contacts of meningitis; that when such contacts are shown to be carriers of the same type of pneumococcus as that infecting the patient, vigorous antiseptic treatment should be instituted, combined with such measures of isolation as conditions permit. In the presence of epidemics of pneumonia or of diseases fatally complicated thereby, such as influenza or measles, it is practical to treat large numbers of men by these methods.

Antipyretic Value of Acetylsalicylic Acid.—Acetylsalicylic acid, in 1 gm. doses, which has no such action in normal persons, Barbour found exhibits a marked antipyretic effect in febrile, temporarily afebrile and convalescent subjects. The antipyretic effect is due essentially to the heat elimination, which is associated with marked perspiration and subjective warmth. Sensitivity of febrile, temporarily afebrile and convalescent subjects to antipyretics is not explained. These drugs do not "stimulate" a "depressed" heat regulating mechanism, nor is sensitivity due to a lack of readily combustible material (glucose); but the respiratory quotient of antipyretic sensitive individuals appears to be increased by doses of acetylsalicylic acid which do not affect the quotient of normal persons.

Mental Disorders Following Influenza.—Gordon's study is based on a series of sixty-two cases, all seen at the end of the febrile period during the phase of asthenia which ordinarily follows infectious diseases. The majority of the cases (forty-four) presented the well known confusional type of psychosis, more or less pronounced. The mental manifestations were particularly marked in persons whose previous medical histories either suggested various episodic phenomena of neuropathic character or contained accounts of actual psychotic disorders. This particular group differed greatly from the groups of cases without previous nervous or mental disorders. Each group is described in detail.

Value of Electrocardiogram.—It is emphasized by Carter and Greene that the electrocardiogram is the only satisfactory clinical method capable of estimating the relative pre-

ponderance of the two ventricles. Combined with the tele-roentgenogram as a guide to gross hypertrophy of the heart, it should furnish the clinician with an increased insight into the question of the mechanics of cardiac response in cases of hypertrophy.

Basal Metabolism in Goiter.—From the work done by Means and Aub it would appear that the safest program for the treatment of exophthalmic goiter, as a whole, is the routine irradiation of thyroid and thymus glands in all cases, with surgery held in reserve for patients who do not then do well. Surgery is contraindicated with patients whose metabolism is rising in spite of complete rest in bed, and also with patients of the type with moderate tachycardia and great metabolism increase, except when they have previously had their thyroid and thymus glands treated by the roentgen ray. The risk of operation is greater, and the need for preoperative roentgen ray treatment is greater in cases with a very high metabolism and moderate tachycardia than in those with an extreme tachycardia and moderate metabolism elevation. In the management of exophthalmic goiter, periodic determination of the basal metabolism should be quite as much a routine as is the examination of the urine for sugar in diabetes mellitus. In borderline cases the basal metabolism furnishes very valuable aid in differential diagnosis.

Overlap of So-Called Protopathic Sensibility as Seen in Peripheral Nerve Lesions. L. J. Pollock, Chicago.—p. 667.

Acute Ascending Paralysis.—The material for this paper consisted of the spinal cords from two cases. Only one patient was seen by Casamajor before death. This man, a soldier, had had a fever for about twenty-four hours, five days before the onset of the paralysis. He suddenly became weak in the knees while working with a pick. He went to his dugout and lay down, and after a few hours was unable to move his legs. The next morning he could not move either legs or arms. He was not incontinent of feces or urine. His arms were completely paralyzed with the exception of the fingers of the right hand, which he could move voluntarily to a slight extent. His pulse was rapid and he had a temperature of 101 F. His breathing was labored and he had a beginning edema of the lungs. The paralysis was of an extreme flaccid type with complete abolition of all reflexes. No sensory loss could be determined anywhere. He died less than three days after the onset of the paralysis. The pathologic findings were practically identical in both cases. In both cases the histologic findings were approximately the same: 1. Hyperemia, hemorrhage edema, and fibrous swelling in the arachnoid; thickening of the pia. 2. No changes in blood vessel walls; no round cell infiltration. 3. Increase of the cellular neuroglia in the central gray, around the root fibers and in the posterior root ganglions. 4. Evidence of beginning degeneration of both a secondary and primary character in the anterior horn cells and some tract cells. Hyperemia of the central gray. 5. Marked degeneration of primary and secondary character of the nerve fibers where they lie in the arachnoid, always most marked in the motor fibers. In the second case there was also a beginning degeneration in the posterior nerve roots just outside the dura and marked degeneration of the posterior root ganglion cells with neuronophagy.

Infective Neuritis.—Kennedy cites four cases revealing definite clinical variants from the well known syndrome of polyneuritis, which, when considered along with the widespread changes in the posterior ganglions, spinal roots, ventral cornual cells and Betz cells of the cortex, would

seem to make it fitting to remove this disease from the neuritides proper, and to designate it by a title more descriptive of the clinical and pathologic picture produced. This condition was described fully by Bradford, Bashford and Wilson in the *Quarterly Journal of Medicine* 12:88, 104 (Oct., 1918, Jan., 1919) and abstracted in *THE JOURNAL*, March 22, 1919, p. 899.

Hereditary Hypothyroidism.—Among sixty-one members of a family belonging to six generations, investigated by Barrett both hair and nails were affected in fourteen instances. The nail defect seemed to be about the same in all, but there was much variation in the degrees of loss of head hair. In the greater number there was an extreme scantiness as to the amount of hair. In no instance was there a total loss of all hair of the head, the most extreme cases showing a fine lanugo-like covering of the scalp. Aside from this particular abnormality, there were other features that showed that in this family group there were conditions active in the production of a variety of disorders that are of much interest to neuropsychiatry. This is the high frequency of feeble-mindedness and neurologic disorders of a degenerate type among the family. The members of the third generation who had dystrophies of nails and hair, and all of their descendants, numbered twenty-nine persons. Of these, twenty-two were definitely abnormal. Twelve of the latter had the characteristic family dystrophy, and ten others, who lacked this, showed other constitutional and nervous disorders. These included one case of epilepsy, one of hysteria, one of severe tic, four instances of feeble-mindedness, one of nocturnal enuresis and four died at an early age from marasmus. Even those who had the nail and hair dystrophy had other abnormalities. One of these was an epileptic; one had cancer; four were feeble-minded, one had nocturnal enuresis. The well known association of abnormalities of hair and of nails in hypothyroidism, and two fairly well defined cases of juvenile myxedema which led to this study, and the reaction of one patient to thyroid feeding, Barrett says, seems to warrant the conclusion that the fundamental disorder in this family was of the thyroid gland.

Antidiphtheritic Serum in Severe Ocular Infections with Special Reference to Hypopyon Keratitis. B. W. Key, New York.—p. 581.

Eye Findings in Lethargic Encephalitis.—Of seven cases reported by Woods two gave history of antecedent influenza, one, a doubtful history, and four, no history of this disease. In only one case was there optic neuritis, and this was of low grade. In three cases there was serious impairment of accommodation, and the pupils were dilated, sluggish and at times inactive. In another case, the patient's age prevented accommodation tests, but the pupils presented similar conditions. These four patients presented other defects; involvement of other branches of the third nerve; abducens and facial paralysis. These cases confirm the observation that the return to normal of the intrinsic muscles is slower than that of the extrinsic muscles. Of special interest were the nystagmoid movements, which occurred in five of these seven cases. In two cases they were the only signs pointing to involvement of the eye muscles.

Intestinal Flagellates: Plea for Their Pathogenicity.

Among the twenty-one cases cited by Barrow there were three cases of intestinal perforation. From one of these, *Trichomonas intestinalis* was recovered, both in the feces and in the peritoneal drainage. He points out that intestinal flagellosis is relatively common in California. Their pathogenicity is not wholly manifested by dysentery, but rather more often by other signs of an absorptive toxemia. No treatment thus far recommended is wholly successful. Calomel, followed by a saline laxative, gives the best temporary relief, but in about ten days' time, a careful search will reveal the parasites again. It is, therefore, necessary to repeat treatment many times. Thymol in large doses has considerable value. Emetin and ipecac exert a helpful influence in most cases. Oil of chenopodium and turpentine are very helpful; enemas of kerosene, ichthyol, or allied substances, have a marked beneficial effect, while those of methylene blue and sodium bicarbonate have about the same relative value as tap water.

Case of Tetanus Successfully Treated by Antitoxin.—During six days of treatment, Jacobson administered 117,000 units of antitoxin; 22,000 units were given intramuscularly; 70,000 units were given intravenously and 25,000 units were given intraspinally. Jacobson favors the administration of antitoxin jointly or alternately intraspinally, intravenously, intramuscularly and locally as being the most rational and promising method of treating tetanus.

Chemotherapeutic Studies on Organic Compounds Containing Mercury and Arsenic. G. W. Raiziss, J. A. Kolmer and J. L. Gavron, Philadelphia.—p. 533.

Effects of Malt and Malt Extracts on Scurvy.—The study made by McClendon and others shows that acidosis has nothing to do with scurvy. Sprouted cereal grains, especially after the acrospire projects one-half inch beyond the grain, are rich in antiscorbutic substance. The antiscorbutic substance in sprouted grain is not destroyed by heating to 70 C. to gelatinize the starch. The antiscorbutic substance may be extracted from sprouted barley after crushing it between steel rolls that are so close together that the cells of the acrospire are crushed.

Toxicity of Phenylacetic Acid.—As a result of feeding excessive doses of phenylacetic acid to a dog, Sherwin and Kennard found that the secreting epithelium of the proximal convoluted tube of the kidney was markedly affected; the endothelium of the blood vessels was not affected; the epithelium of the arched collecting tubule showed evidence of a destructive action, while that of the straight collecting tubule appeared to escape. The secreting epithelium of the

limbs of Henle's loop was most distinctly involved. The interstitial tissue of the kidney was found not to be injured, and the liver changes, the authors believe, are in all probability secondary.

Chemical Identification of Thyroxin.—In this, the second paper of a series, Kendall and Osterberg report in detail on the most important physical and chemical properties of thyroxin.

Carbonates in Cow's Milk.—In the case of twenty-five samples of milk drawn from separate quarters of the udder, Van Slyke and Baker found that the CO_2 varies from 7 per cent. by volume to 86 per cent.; the p_{H} value varies from 6.50 to 7.16, in a general way increasing with the CO_2 content; the degree of acidity, as measured by titration, tends to decrease with increase of CO_2 content. In comparison with the results of other workers, the results obtained by us are higher. The CO_2 content of normal milk appears to be about 10 per cent. by volume.

Variations in Reaction of Fresh Milk.—The object of this investigation was the study of the extent and causes of the variation of the hydrogen ion concentration in freshly drawn cow's milk.

Activity of Lung Extract.—The strong coagulative activity of lung and kidney tissues, and to a lesser degree of skin, Mills says, is suggestive of a possible protective mechanism against hemorrhage.

Nutritive Value of Banana.—According to Sugiura and Benedict, a diet consisting of bananas, 83.0 per cent., casein, 16.0 per cent., yeast, 0.5 per cent., and protein-free milk, 0.5 per cent., is an adequate diet for the growth, maintenance, reproduction and perfect milk production of the albino rats.

Treatment (?) of Psoriasis. W. A. Pusey, Chicago.—p. 791.

Treatment (?) of Psoriasis.—Pusey records a case which illustrates the futility of most of the empiric treatments for psoriasis to which the patient had submitted in the course of three years. The patient had been given emetin, arsphenamin, staphylococcus and streptococcus vaccine, Fowler's solution and autoserum. He had been on as strict a non-protein diet as he could devise for himself for seven months. He had his tonsils removed, seven teeth extracted and then had a few roentgen-ray exposures. In spite of these measures, the psoriasis showed no improvement; in fact, no material change of any sort.

Old Strain of Connective Tissue in Culture.—A fragment of heart extirpated from a chick embryo, Jan. 17, 1912, is still alive. It has been under cultivation in vitro for a period of over seven years and has undergone 1,390 passages. Ebeling describes the technic employed in perpetuating the strain during the last five years and in measuring the increase of the tissue, the factors which influence the rate of growth, and the present condition of the strain. The medium

used for perpetuating the strain is composed of equal volumes of chicken plasma and chick embryo extract.

Pfeiffer's Bacillus and Influenza.—The serums of patients convalescent from influenza yield reactions for agglutinins, precipitins, and complement binding bodies with antigens of Pfeiffer's bacillus. These reactions appear constantly at the end of the first week, increase in intensity during the second week, and remain demonstrable for a period of from two to four months. They were most complete in the serum of patients suffering from postinfluenzal pneumonia. It is also demonstrated by Wollstein that the strains of Pfeiffer's bacillus isolated during the epidemic were morphologically and biologically similar to the strains isolated from influenza cases in other years, and antigenically they differed from them only quantitatively. The patients' serologic reactions indicate the parasitic nature of the bacillus, but are not sufficiently stable and clean cut to signify that Pfeiffer's bacillus is the specific inciting agent of epidemic influenza. They do, however, indicate that the bacillus of Pfeiffer is at least a very common secondary invader in influenza, and that its presence influences the course of the pathologic process.

Antiblastic Phenomena in Immunity to Pneumococcus.—Barber gives the results of a series of experiments made with a special technic for the purpose of testing whether or not so-called antiblastic phenomena or bactericidal phenomena play any part in immunity to pneumococcus.

Production of an Antihemotoxin for Hemotoxin of Bacterium Welchii (Bacillus Aerogenes Capsulatus). W. W. Ford and G. H. Williams, Baltimore.—p. 385.

Testing Antityphoid Serum.—The new method of testing typhoid antiserums worked out by Fukuhara and Yoshioka is as follows: With the use of an arbitrary protective unit of antiserum (standard serum), the L_5 dose of a typhoid culture is determined; with this L_5 dose see p. 290 the serum to be tested is mixed in varying quantities; the largest amount of the serum which will just permit the death of a guinea-pig of 250 gm. weight within twenty-four hours after the mixture has been injected into the peritoneal cavity is taken as the protective unit. The value of an antityphoid serum is expressed by the number of such protective units contained in 1 c.c. of the serum. Any strain of typhoid bacteria can be used for the test. The virulence control is not important.

Testing Antitoxic Dysentery Serum.—In order to determine the antitoxic value of antidysentery serum it is necessary to select a standard serum which can be preserved in a dry state in the vacuum tubes of Ehrlich. The standard antitoxin unit adopted by Fukuhara was the amount that neutralized 100 minimal lethal doses of the toxin which at that time was available. For the testing of other antidysentery serum the so-called L_5 dose of dysentery toxin was adopted as the smallest amount which when mixed with the antitoxin unit and injected intravenously into a rabbit of 1,500 to 2,000 gm. weight caused the death of the animal within from four to five days. The L_5 dose of the toxin is employed, in the usual manner, to determine the relative antitoxic value of newly prepared antiserum.

Antigenic Property of Pfeiffer Bacillus.—During the height of the epidemic of influenza in New Orleans more

than 5,000 persons were vaccinated by Duval and Harris with a specially prepared protein suspension of the Pfeiffer bacillus. Of this number approximately 90 per cent. did not contract influenza, either during the period of the epidemic or its recrudescence which occurred two months afterward. The culture used in the preparation of the vaccine was grown on the surface of hemoglobin nutrient agar at a temperature of 37 C. for from thirty-six to forty-eight hours, when the growth was washed off and suspended in physiologic sodium chlorid solution and immediately devitalized by being saturated with chemically pure chloroform.

Poisons of the Influenza Bacillus.—While the evidence obtained by Parker is by no means conclusive, it seems probable that the poison of *B. influenzae* contains two poisons; the first, the more important one, a true soluble toxin, filtrable, thermolabile, against which antitoxins can be produced; the second, present also in the vaccine of *B. influenzae*, also filtrable, but differing from the first poison in its thermostability, and in the fact that it is not detoxicated by the antitoxin.

Multiplicity of Races of *B. Influenzae*.—The results recorded by Valentine and Cooper are held to indicate that under the term *B. influenzae* are included a group of organisms which, for practical purposes, is heterogeneous in character as determined by immunologic reactions. The existence of a multiplicity of races is advanced as evidence that *B. influenzae* is not the primary etiologic agent in epidemic influenza.

- *Complement Fixation with Acid Fast Bacteria. III. Tuberculosis. J. V. Cooke, New York.—p. 491.
- *Amebic Dysentery in California. W. W. Cort and J. D. McDonald, Berkeley.—p. 501.
- Streptolysin. Y. Nakayama, Chicago.—p. 509.

Pathogenicity of *Bacillus Influenzae*.—The Pfeiffer influenza bacillus was found by Albert and Kelman to be distinctly pathogenic to mice, guinea-pigs and rabbits. Although the symptoms of intoxication as seen in lower animals following injections of the Pfeiffer bacillus are suggestive of the profound intoxication seen in connection with many cases of the epidemic disease influenza in the human being, the authors feel that their experiments do not furnish any proof that the Pfeiffer bacillus has any specific etiologic relationship to that disease. On the other hand, they suggest that a possible etiologic relationship cannot be ignored.

Reaction of Culture Mediums.—According to Fennel and Fisher the adjustment of bacteriologic culture mediums according to hydrogen-ion concentration, because of its accuracy and simplicity, should wholly supplant the phenolphthalein (total acidity) method.

Complement Fixation in Leprosy.—In a study of twenty cases of leprosy of the nodular, macular, nerve and mixed type, Cooke found that leper serums contain complement binding substances that react with antigens of acid fast bacilli and give an acid fast fixation similar to that obtained with serums of rabbits immunized with acid fast organisms. Some serums contain these antibodies in rather high concentration, notably those from cases of the nodular type of the disease; other serums show a relatively low antibody content. The serums of high titer may give a nonspecific fixation also with nonacid fast antigens and with lipoidal (Wassermann) antigen, but only in comparatively low dilutions. It is suggested that this attribute of such high titer leper serums may explain in a certain percentage of positive Wassermann reactions described in leprosy. The acid fast reaction given by leper serums with acid fast bacterial antigens prevents the use of the complement fixation reaction

in obtaining evidence of the etiologic importance of any acid fast organism isolated from leprosy.

Complement Fixation in Tuberculosis.—In tuberculosis, the serum contains complement binding substances that give fixation when members of the acid fast group of bacteria are used as antigen. These antibodies show a considerable difference in concentration in different serums, but this difference in titer does not correspond with the severity of the infection in the different cases. A relatively small percentage of patients with active tuberculosis have too small an amount of complement fixing antibody to be recognized in the test. These cases are analogous to those of syphilis that give a negative Wassermann reaction. Cooke found the test of some value in calling attention to unrecognized tuberculosis, but it does not always indicate a clinically active process. Leprosy and tuberculosis are the only human infections that give the reaction, and since it is specific for the acid fast group of bacteria, the term acid fast fixation seems appropriate.

Amebic Dysentery in California.—As a result of a circular letter sent out by the California State Board of Health a total of fifteen cases of amebic dysentery were reported from eight hospitals. No cases of dysentery caused by flagellate protozoans were reported.

Therapeutics of *Aspidosperma*.—Wilcox considers this drug a valuable remedy when the respiration is embarrassed, as in emphysema, chronic bronchitis or chronic pneumonia. Given in proper doses, it relieves not only the dyspnea but also the cyanosis and sense of suffocation. It appears to assist the oxygenation of the blood as well as to stimulate the respiratory center. *Aspidospermine* represents fairly well the activity of the drug with the further advantage that it may be used hypodermically in a dose of one-half grain (0.03 gm.).

Treatment of Burns. A. W. Hengerer, Buffalo.—p. 988.

Treatment of Burns.—In every case of severe burn, Hengerer immediately gives full dose of morphin. Then he covers the damaged area with a clean towel or absorbent cotton, gets the patient to the hospital as soon as possible, administers an anesthetic and removes the damaged tissue by scrubbing the burned area with ordinary hand brushes until the surface appears to be covered with normal tissue. In scrubbing the burned area, the object is to remove all of the destroyed tissue. The scrubbing should be done as soon after the burn has occurred as possible but the length of time is not necessarily a contraindication. Hengerer has scrubbed burns three days after their occurrence with happy results. Brushes are changed frequently and aspsis should be employed as much as possible. The wound may then be dressed with a thick covering of petrolatum on gauze on which a small amount of bismuth subiodid is sprinkled, or the wound may be covered with wax. Hengerer claims that patients with over one half of the body burned have been saved by this treatment, and that the resulting horrible deformities and disfiguration so often seen were greatly lessened. The dressings are bearable and often painless, the time of convalescence is greatly shortened. Hengerer terms this the surgical treatment of burns.

Attitude of General Practitioner.—This paper was abstracted in THE JOURNAL, Nov. 8, 1919, p. 1468.

Value of High Rectal Enema.—This paper was abstracted in THE JOURNAL, Nov. 8, 1919, p. 1467.

Cancer of Esophagus.—Patterson advocates endoscopic examination in these cases, but warns that before any person is examined esophagoscopically it is of paramount importance to study the esophagus by means of fluoroscopy and roentgenoscopy in order to exclude aneurysm and to observe any hesitance in the normal function of the esophagus or obstruction in the passage of the barium meal through the esophagus. Three cases are reported.

Foot Prophylaxis in Childhood.—The prevention of foot disability in children, Rugh says, centers about two great classes of conditions, viz., the congenital and the acquired. Under all conditions, however, whether congenital or acquired, intrinsic (within the foot) or extrinsic (without the foot), fully 98 per cent. of disabilities in the foot in childhood (as, indeed, also in adults) are mechanical both in origin and in character. Every case examined must be looked at with this fact in mind, and whatever the type of the disability, its mechanics must be recognized and proper treatment advised. The various types of foot disorder and their treatment are discussed by Rugh.

Diathermy in Mouth Cancer.—In the treatment of epithelioma of the mouth and pharynx, Patterson regards diathermy as the best method to adopt in all cases, not only in cases on the borderland of being inoperable by the knife. No excision of a carcinomatous growth in the tongue, mouth or pharynx, however small that growth may be, should be carried out with the knife if diathermy is available. Encouraged by the good results in cases where the disease was limited, Patterson has applied the method in advanced cases where nothing could really be expected from treatment of any kind. The results in selected cases have been extraordinarily good. Patterson believes that if patients could only be seen early enough a large number of cures would probably be effected. It has been too much the habit, he says, and it is still too much the habit of surgeons to regard this method as a palliative measure only, and as one to be reserved for "inoperable" cases.

Right Inguinal Hernia Following Appendectomy.—Griffiths has collected eleven cases of inguinal hernia following appendectomy. Of these, ten were on the right side and the eleventh appeared as a left inguinal hernia. The date of appearance of these hernias varied from a few months to three and one half years after appendectomy was performed. In one case the hernia followed twelve years after operation, but this case had also been complicated by an operation for ventral hernia in the old scar. This late occurrence may account for this end result or complication having passed unnoticed so long. In ten of the cases the gridiron incision was used, none of the incisions being near the outer border of the right rectus muscle. In the eleventh case, a Battle's scar was present, the hernia having appeared eighteen months after operation. The length of the scars varied from two and one half inches to a maximum of six inches. The situation, too, differed somewhat in position, from immediately above Poupart's ligament and the right iliac crest to near the midpoint between the right anterior superior spine and the umbilicus. The hernias were mostly small. The greater majority of the original operations for appendicitis had not required draining for pus, and the incision had been closed in the ordinary way. In explanation of this occurrence, Griffiths suggests that it may occur in two ways, either by avulsion or division of the fine muscular nerve twigs to the lower portions of the internal oblique and transversalis muscles during the opening of the peritoneal cavity, and leading to a partial or complete atrophy of the muscle fibers in the region of the internal abdominal ring; or, on the other hand, by compression of the same nerves

by the encircling catgut sutures in sewing up the incisions in the transversalis and internal oblique muscles, in repairing the abdomen after appendectomy.

Unusual Form of Ventral Hernia.—In Apperly's case the hernia protruded from the site of an artificial anus, made about six inches above the cecum. Part of the wall of the colon had been forced through the colostomy opening, and by stretching and turning inside out, formed the sac of a hernia, the content of which was a loop of gangrenous small intestine 10 inches long. The mucous membrane of the colon was so stretched and shining as to be indistinguishable from peritoneum. The gangrenous contents of the sac were readily removed when relieved from constriction and were resected. A lateral anastomosis was made, the colostomy being returned to its normal position.

Serum of Patient with Reference to Wassermann's Test. R. Kobayashi.

Cultivation of Spirochete of Weil's Disease.—Wataguchi succeeded in cultivating the spirochete of Weil's disease on a watery mixture of the blood. Guinea-pig inoculation with these cultures resulted in a reproduction of the disease, and an immunizing serum was obtained from rabbits. Specific immune bodies were found, and immunity was conferred by injection. All this work was done on animals. Further work is now in progress to apply these findings to human beings.

Penetration of Drugs Into Spinal Cavity and Their Disposal.—Iodin and hexamethylenamin were found in the urine by Hashimoto after injection of small amounts into the cerebrospinal fluid. However, it was more difficult to detect iodine in the cerebrospinal fluid, no matter whether given by mouth or intravenously, than was the case with hexamethylenamin. The penetration of these drugs seems to depend on the degree of the pathologic changes present. The greater the change, the less the degree of penetrability. Hashimoto claims that this finding is of value clinically.

A Case of Urethral Calculus. P. S. Clarke, Sydney.—p. 417.

Transmission of Leprosy to a Monkey.—Bradley reports on the inoculation of a monkey, *Macacus rhesus*, with leprosy material, and the subsequent development of nodular granulomatous lesions. The material was obtained from a nonulcerated lesion on the eyebrow of a leper. Numerous attempts were made on half of this piece of tissue for cultural purposes by Noguchi's and other methods, anaerobic and aerobic, but in all cases contamination occurred and the cultures were discarded. The remainder of the tissue was used for inoculating the monkey. Sixty days later the disease was seen to have developed. Smear preparations from three lesions showed leprosy bacilli in each one. A few days later the monkey was found dead. A thorough postmortem examination was made. Lepa bacilli were found in the axillary and inguinal glands, and in the spleen.

Exophthalmic Goiter Combined with Myasthenia.—The outstanding feature in Rennie's case is the survival for a period of at least thirteen years of a patient suffering from a combination of the symptoms of two diseases, each of which is considered to have a grave prognosis; and not only a survival after these many years, but a practical recovery of a large amount of health and strength. A second point is the permanence of some defect of the external ocular muscles.

*Malignant Measles: Two Cases. H. V. O'Shea.—p. 460.
*Delayed Tetanus, with an Unusual Complication. H. K. V. Soltan.—p. 467.

Caesarean Section in Osteomalacia.—This article is based on seventy-three cases of caesarean section with seventeen deaths, a mortality of 23.3 per cent. Neve points out that these osteomalacia patients are poor subjects for operation; therefore even better results may be expected in other maternity cases. He advocates the judicious but extended use of this method of delivery. In any case, he considers craniotomy of a living child as little short of homicide.

Malignant Measles.—The first case cited by O'Shea was one of hemorrhagic measles. Although the nervous symptoms were well marked, approaching the "status typhosus," the most remarkable feature was the extensive hemorrhages, petechial and otherwise, which occurred throughout the body. Contrary to the usual issue, death, the patient recovered. The second case is an example of the toxic type of the infection, which was characterized by a badly developed rash, not well raised above the skin and of a bluish tint. The rash was of the dark malignant type, and hot mustard baths and diaphoresis failed to bring it out properly. Symptoms of meningitis showed themselves on the fourth day, and the condition of the patient became hopeless. Toward the end edema of the lungs set in with the failing circulation, preceded by hyperpyrexia and convulsions. Treatment was of no avail. The child died.

Tetanus with Unusual Complication.—A retained foreign body—subsequently removed—was probably the source of delayed tetanus in Soltan's case, but the interesting feature was not related to the tetanus. The man developed a small abscess, situated just behind the right trochanter. It was opened and drained a week later. Another incision over his right buttock opened up a collection of pus beneath the gluteus maximus. While swabbing out the abscess cavity, a dead worm, covered with blood clot, was removed on the gauze. The worm was 4 inches long, and, after investigation by the pathologist, was pronounced to be a male *Ascaris lumbricoides*. The stools were subsequently examined several times for ova, but only at the first examination, two days later, were any found, and these were ova of *Ascaris lumbricoides*.

- *Allowing Parturients to Get Up Early. Bourcart (Geneva).—p. 465.
Idem. Brouha (Liège).—p. 487.

Allowing Patients to Get Up Early.—Bourcart gives four pages of bibliography, set solid, to sustain the advantages of allowing normal parturients to get up early, as also the patients after operations. The abdominal balance must be restored, however, he says, before patients are allowed to get up. This can be promoted by massage, exercising the

abdominal muscles, to reestablish the normal course of the blood. Vibratory massage below the liver is particularly useful for this. A semiseated position or reclining on the side helps further to hasten conditions which permit getting up. The abdominal massage should be done by the physician; usually four or five minutes twice a day are enough at first in hospital practice. After operations for ileus the manual vibratory massage is very useful, possibly warding off peritonitis. Turning to the prone or knee-chest position is also useful.

Allowing Parturients to Get Up Early.—Brouha insists that the getting up should be individual and progressive. The accoucheur must be the one to decide the question in each case, with the intelligent collaboration of the parturient herself and the nurse. This restricts the method, he admits, to the privileged classes, especially as tradition is all against it, and the family usually combat it and ascribe every mishap to the physician's getting the patient up too early. Working women are more robust and bear without harm the inconvenience of overlong staying in bed.

Bulletin de l'Académie de Médecine, Paris

Nov. 18, 1919, 82, No. 36

- General Prophylaxis of Tuberculosis. J. Lignières.—p. 301.
*Pulmonary Mycosis. A. Sartory.—p. 304.
*Intraspinal General Anesthesia. Paul Delmas.—p. 305.
*Mites in Barley. Loir and Legangneux.—p. 308.
*Open Tuberculosis in Dogs and Cats. Gabriel Petit.—p. 310.
*Gas Cysts of the Intestines and Peritoneum. M. Letulle.—p. 315.

Pulmonary Mycosis.—Sartory describes an aspergillus recently cultivated from the sputum of a pulmonary tuberculosis suspect.

Intraspinal General Analgesia.—Delmas states that 600 operations done under his intraspinal technic without a single untoward feature have convinced him of its superiority to other methods whenever general inhalation anesthesia is contraindicated. He dissolves the cocain cold in the patient's own cerebrospinal fluid and injects it at once through a needle 7 cm. long by $1\frac{1}{10}$ mm. interior diameter. The analgesia lasts for about an hour (1 cg. = one-fourth hour). He says that the motor and sensory nerves are not touched, and there are no immediate or remote by-effects. The only precaution necessary is that the patient must not sit up for twenty-four hours.

Barley Mite Eruption.—Sixty-three men unloading a cargo of barley, just arrived from the near East, developed in two or three hours a confluent eruption which was traced to an acarus of the pediculoides group. The eruption yielded to treatment for scabies. Six similar epidemics have been recorded at Havre since 1911. Preventive measures should include sulphur fumigation of the vessel hold, and douches, with change of clothing, for the dock workers.

Tuberculosis in Dogs and Cats.—Petit expatiates on the facility with which human tuberculosis is transmitted to dogs and cats, and the danger of infection from those with intestinal, pulmonary and skin discharging lesions. Any dog or cat should be regarded with suspicion when it is growing thin and coughs, or has a diarrhea or persisting ulceration on the face or neck. The pus from these latter lesions in particular swarms with tubercle bacilli.

Gas Cysts in the Intestines.—Letulle describes with seventeen photomicrographs the histopathogenesis in four cases of gas cysts in bowel and peritoneum.

arm of the pupil reflex, not necessarily of syphilitic origin, or in tabes, or general paralysis.

Paris Médical

Nov. 29, 1919, 9, No. 48

*Opening Lecture of Course on History of Medicine and Surgery. Menetrier.—p. 417.

*Determination of Acidity of Gastric Juice, P. Baufile.—p. 428.

History of Medicine.—Menetrier devotes most of his inaugural lecture to Laennec and the centennial of his work, "L'Auscultation médiate," although auscultation is now usually direct and not "médiate" as he described. Menetrier adds, "As Laennec had been for eighteen years an ardent student of pathologic anatomy, the findings with his new method of exploration explained the lesions to such an extent that he may be called the creator of modern pathology."

Acidity of the Gastric Juice.—Baufile comments on the error resulting from the assumption that the stomach contents obtained after a test meal represent pure gastric secretion. In reality they represent the admixture of gastric juice and what is left of the test meal lingering in the stomach. This admixture varies within a wide range as one or the other of these elements fluctuates, and the proportion of each should be determined. This can be readily accomplished by incorporating with the test meal some substance which does not modify gastric secretion and which is not absorbed by the gastric mucosa. Subtracting the amount of this substance in the stomach contents one hour after taking the test meal, leaves the gastric secretion alone. The substance answering the above conditions may be sodium phosphate (Mathieu and J. C. Roux) or ferric sulphate (Meunier). He prefers the latter. For example, after an Ewald test meal of 340 c.c. extraction of the stomach contents gives 270 c.c. Estimation of the iron in this stomach contents shows that 90 c.c. is what is left of the test meal, and 180 c.c. is the amount of stomach secretion. Applying the Töpfer test this gives 0.584 free hydrochloric acid; 0.146 acid of fermentation; 0.438 combined acid, and total acidity of 1.168 per thousand cubic centimeters. If 180 c.c. of pure gastric juice is found in 270 c.c. of chyme, and 1 c.c. of gastric juice is equal to $\frac{270}{180}$ c.c. of chyme, then 1,000 c.c. is

equal to $\frac{270}{180} \times 1,000 = 1,500$ c.c. The formula is thus $A \times \frac{C}{S}$ (chyme)
(acidity) $\times \frac{S}{C}$ (gastric juice). This formula is accurate

enough for all practical purposes, while the technic is so simple, Baufile emphasizes, that it should become a routine procedure.

Presse Médicale, Paris

Nov. 26, 1919, 27, No. 71

*Acute Aseptic Purulent Arthritis. E. Apert and Cambassédès.—p. 713.
*Urobilinuria. Brulé.—p. 714.

Aseptic Purulent Arthritis.—Apert and Cambassédès have encountered two cases in which an acute arthritis of the knee in children seemed to be absolutely aseptic, although puncture brought pus. They cite a third case in which the elbow was the seat of the lesion. Recovery was soon complete and permanent in all. The pus coagulated *en masse*, the fibrin not being destroyed by bacterial action as with ordinary arthritis. The absence of fever—in marked contrast to the swelling of the joint—is also characteristic but is not invariable; in one of the cases there was temperature of 39 C., but a concomitant meningitis was probably responsible for this. Pain occurs only when the joint is very much distended. In one of the children there was no pain, and the arthritis was discovered only by accident during convalescence from scarlet fever. No treatment was attempted in these cases beyond the exploratory puncture, done twice in one case.

Urobilinuria.—Brulé reviews the conflicting views on the origin and clinical significance of urobilinuria. His opinion

is that it signifies retention of bile pigments, but the retention is not intense enough for bilirubin to appear in the urine. This retention may be due to lesions in the liver or biliary passages or to hemolytic processes. He never found urobilinuria in normal subjects. By examining the urine for bile salts, as well as for urobilin, we may throw light on the cause of the retention. With obstruction in the biliary passages, the icterus is never dissociated, while with hemolytic icterus there is always dissociation. With liver disease the retention may be complete or dissociated. There may be retention without jaundice, and urobilinuria may be the only sign to warn that the liver is touched. It should be excluded before accepting a pigmentary acholia. Examination for stercobilin is also important as its absence proves that no bile is passing into the feces even when the stools seem of normal color. A further test of this is to examine the blood dust or the fat in the blood after test ingestion of fat.

*The Teaching of Obstetrics at Paris. A. Couvelaire.—p. 721.

*Rapid Clinical Tests for Albuminuria and Glycosuria. L. Bauzil.—p. 725.

*Gas Cysts in the Mesentery. Cristol and Porte.—p. 726.

Teaching of Obstetrics at Paris.—Couvelaire reviews the history of the teaching of obstetrics at Paris from the founder of modern obstetrical surgery, the barber-accoucheur, Ambroise Paré (1541) to Tarnier (1857) and the modern school. In conclusion he emphasizes that the science of obstetrics is the science of the generation of man, not merely the science of labor alone.

Tests for Albumin and Sugar in the Urine.—Bauzil describes how he has simplified the technic for these tests so that any practitioner can determine the proportion of albumin and sugar in the urine rapidly and readily with approximate precision.

Gas Cysts in the Abdomen.—Cristol and Porte report a case in which an emergency laparotomy was required for sudden intense abdominal pain and vomiting of bile; pulse 100; the abdomen distended with gas. The dilated stomach reached to the pubis, and puncture released gas and 4 liters of a blackish fluid. The mesentery was found studded with small gas cysts and it had strangulated the bowel close to the pylorus. Almost the entire mesentery was studded with thousands of these pearly cysts of different sizes. The abdomen was merely sutured, but the admission of air seems to have been responsible for the subsidence of the cysts, as there have been no further symptoms since. The woman's health has been apparently perfect during the year to date.

*Sodium Bromid in Pathologic Conditions in the Digestive and Circulatory Apparatus. P. M. Besse and P. Goutzait.—p. 483.

The Blood Pressure in Psychoses.—Euzière and Margarot refer to what they call anxious states in persons without organic lesions. The arterial pressure is often high, rising proportionally to the feeling of distress. Sympathicotomy is evident in the more pronounced cases, and this readily explains the high arterial tension by vasoconstriction.

The Sacro-Iliac Articulation.—Pilatte and Vignes discuss the anatomy and physiology of this articulation, and the interpretation of symptoms in case of pathologic changes.

*Early Diagnosis of Gastric and Duodenal Ulcer. H. García Lagos.—p. 532.
Influenzal Pneumonia. A. Ricaldoni.—p. 553.

Hypertension.—Vaquez defines hypertension as a blood pressure above 150 or 160 in men and 140 or 150 in women. Age in itself does not entail hypertension; he has one woman patient who is almost a centenarian but her blood pressure keeps below 140. The most effectual remedy for paroxysmal hypertension, he reiterates, is venesection; this permanently reduces the pressure if 700 or 800 gm. of blood are withdrawn. Lumbar puncture has sometimes given good results in treatment of the intense headache from hypertension, but he shares Osler's skepticism in respect to the action of drugs except in transient emergencies.

The Cerebrospinal Fluid in Differential Diagnosis.—Araújo enumerates the characteristic findings in the fluid in different pathologic conditions and especially in meningeal states of doubtful origin. In one child the somewhat sudden onset of what seemed to be tuberculous meningitis and the early semiunconsciousness suggested a doubt, and under mercurial treatment recovery was soon complete. It was learned later that the father was syphilitic. Another child developed the symptoms of tuberculous meningitis but the lumbar puncture fluid showed high proportions of albumin and urea, and the child improved under treatment to such a degree that the diagnosis was rendered uncertain. The urine and eye findings were normal. Two weeks later the headache returned with convulsions, and the puncture fluid then showed 7.4 per thousand chlorids and 3.45 urea, and necropsy disclosed tuberculous pyelonephritis but no meningeal lesions. Otitis is often misleading, but the lumbar puncture fluid will exclude meningitis, and when the ears are drained the meningeal symptoms may subside.

Epinephrin in Asthma.—Maira reiterates that many years of experience have convinced him that epinephrin is the treatment *par excellence* for combating attacks of asthma. These patients stand large doses. One had suffered from asthma for fifteen years when subcutaneous injections of epinephrin were begun in 1914, with prompt relief for several hours. The dose was 15 drops, and it was repeated twice

and sometimes three or four times a day. This has been kept up for five years, with more than 300 injections, and no by-effects have been observed. Maira has seen nothing to indicate that epinephrin brings on arteriosclerosis when given by subcutaneous or intramuscular injection. The latter is preferable when rapid action is desired. He has obtained good results with it also in whooping cough.

Early Diagnosis of Gastric and Duodenal Ulcers.—García emphasizes that it is the succession of the symptoms, their occurrence through weeks, their connection with the meals, and the possible remissions—up to ten years in one of his cases—that give the clue before the classic triad of symptoms of ulcer develop. The symptoms differ in different patients but the attacks in the same patient are almost all alike.

- *Treatment of Epidemic Poliomyelitis. F. Vidal Solares and J. F. Ayguavives.—p. 177.
*Acute Rheumatism in Children. Joaquín Puchades.—p. 188.

Treatment of Epidemic Poliomyelitis.—Vidal and Ayguavives wait for the acute phase to be over, and then give hypodermic injections of strychnin plus application of electricity. This seems to ward off the atrophy of the muscles. They test the child's susceptibility to the strychnin with 0.25 mg. first. If this does not induce trismus, they increase by the same amount until the child is getting 1 mg. in this way, which is kept up for five days. At the seventh day they give 0.5 mg. and increase in a week to 1.5 mg. This is kept up for ten days if no signs of intoxication are evident. At the twenty-third day the drug is suspended for two weeks but the electric sittings and massage are continued. It is then resumed. Two cases are described. One child of 3 is now walking well after 125 injections of the strychnin; the other child of not quite 2 shows great tendency to improvement after six months of the faradic current, then, after this, galvanic sittings, and the injections of strychnin.

Acute Rheumatism in Children.—Puchades comments on Langmead's examination of 2,556 schoolchildren at London for signs of rheumatism. The findings were positive in 5.20 per cent. of all the children, and 87 per cent. with positive findings had some heart lesion, although all of the children examined were supposedly healthy, and no precautions to guard the heart were being taken. Hence Puchades emphasizes that rheumatism is far more prevalent among children than is generally recognized, and that when a child has acute rheumatism, repose afterward should be enforced for a much longer period than the stay in the public hospital. The child should not be allowed to go home as soon as the acute phase is past as the heart may become irreparably damaged, if further repose is not enforced. The rheumatism may develop insidiously and not be recognized in time to ward off damage by appropriate treatment. Medical school inspectors should be on the alert to detect the disease in its incipency.

- *Albee's Operation in Pott's Disease. T. R. de Mata.—p. 117.
Prophylaxis of Tuberculosis on Ships. Medardo Rivera.—p. 123.

Albee's Operation for Vertebral Tuberculosis.—De Mata is convinced that the implant made according to Albee's technic heals in place just as a simple fracture of a long bone heals. His roentgenograms have confirmed this, as also his clinical experience. The Albee method seems better adapted for the poor. For those who can spare the time, he prefers heliotherapy and other medical measures, although

his experience with it in thirty-five cases has been absolutely favorable. The interval since has been over four months in thirty of the cases. One man required a new operation six months later as the implant had fractured at the vertex of the kyphosis. The broken off fragment had become necrotic, but all the rest formed a solid living whole with the spine, and a second small implant restored clinically normal conditions. The reappearance of pain testifies to fracture of the implant. Two of his patients had paraplegia from compression, and this has not been modified in any way by the implant. The article is illustrated.

Tuberculin Inunctions in Prophylaxis of Tuberculosis. S. de Madrid.—p. 139.
The Arrhythmias. P. M. Barlaro.—p. 140. Cont'n.

Action of Snake Venom on Coagulation of the Blood.—In the course of their years of research on snake venoms, Housay and Sordelli found that all of the twenty-two venoms investigated destroyed the cytozym in the blood, that is, the substance which combines with the serozym and calcium to form thrombin. With the cytozym destroyed, no thrombin can form, and hence there can be no coagulation. This is the case with cobra and certain other venoms, but the lachesis and crotalus venoms (Argentine species) possess a special coagulating property which coagulates even citrated blood. Their research has demonstrated further an extremely active precipitation of fibrin under these latter circumstances, as if to protect the erythrocytes with a varnish of fibrin against the active coagulating agent circulating in the blood. This protecting mechanism of temporary defibrination is interesting from the standpoint of the phenomena of immunity, they add.

- *Pregnancy in Double Uterus. Alvaro Esquerdo.—p. 533.
*Preventive Vaccination Against Influenza. A. Salvat.—p. 538.
Spontaneous Rupture of the Aorta. A. Aguilar Feliu.—p. 542.
*Drainage of the Bile Ducts. E. Ribas y Ribas.—p. 546.

Pregnancy in Double Uterus.—Alvaro Esquerdo's patient had pains in the lower abdomen after an apparently normal rapid delivery, and a tumor was palpated. It was assumed to be a large fibroma until puncture a month later released thick black blood, and the diagnosis was changed to sarcoma. The laparotomy revealed accumulation of blood in the right half of a double uterus and prompt recovery followed panhysterectomy. He has encountered a number of cases of double uterus with hematometra, once in a virgin. With anomalies of this kind there are usually other malformations, so that panhysterectomy is generally advisable on account of the special tendency to complications. However, he adds, if the hematometra in the double uterus can be correctly diagnosed and amply drained without operative intervention, this might be tried to begin with.

Preventive Vaccination Against Influenza.—Salvat published in 1918 his successful vaccination of 4,900 Spanish subjects none of whom developed fatal influenza thereafter, but five had severe complications in a group of fifty English subjects vaccinated at the same time. He theorizes to explain this difference in the two groups, and claims priority for this prophylactic vaccination to ward off grave complications.

Drainage of Bile Ducts.—Ribas analyzes his 118 gallstone operations, and commends his practice of draining whenever the symptoms seem to come from the gallbladder alone, unless there is merely one gallstone.

Roentgen Treatment of Uterine Myomas. P. González Duarte.—p. 352.

Obstetric Manikin.—Beruti gives ten illustrations of his obstetric machine which reproduces the mechanism of delivery.

Microbiologic Action of Roentgen Rays.—Vilaplana's histologic research was restricted to female genital organs, human and guinea-pig ovaries, and cancerous cervix tissue, before and after raying. The cancer cells pass rapidly through three phases, first the enlargement of the cells, then their degeneration, without karyokinesis. The degenerative cycle is exceptionally rapid and tenacious. Sarcoma cells are destroyed so rapidly that large amounts of toxins are poured out and may do great damage. In one case of uterine myoma the reaction to raying was so severe that the patient insisted on hysterectomy instead, and the microscope disclosed sarcoma nodules in the fibroma.

- Obstetric Manikin. J. A. Beruti (Buenos Aires).—p. 231. See above.
*Pregnancy Pyelitis. J. Adeodato.—p. 245.

Pregnancy Pyelitis.—Adeodato reports four cases from his service at Bahia during the last eight years, but he is convinced that routine microscopic examination of the urine would reveal that pyelitis is far more common than generally supposed. Even when fever and pains attract attention they are liable to be attributed to other causes, and as the pyelitis is generally thrown off after delivery, it escapes detection. In two of his cases the disturbances had been ascribed to malaria, and the patient was about to be stuffed with quinin when the microscope revealed the true state of the matter. If the pyelitis is not recognized, it may become aggravated by treatment on a mistaken basis, and be forced into a chronic phase or at least into conditions favoring return at each pregnancy.

Blocking the Nerves for Operations on the Limbs.—Alvaro de Figueiredo gives minute directions for blocking the various trunk nerves, and states that in his experience healing afterward was normal and there was no special tendency to nervous disturbances. The great drawback to local anesthesia is the dread and worry from the sight of the operation, but two or three whiffs of ether put an end to this. He gives the details of ten cases to demonstrate the great advantages of regional anesthesia for both children and adults.

August, 1919, 27, No. 8

- *Isolation of Lepers. E. Rabello and Silva Araujo, Jr.—p. 271.
*Hemorrhagic Purpura. Cardoso Fonte.—p. 281.

Isolation of Lepers.—This is a committee report on the question whether it is advisable to leave lepers in their homes under special surveillance or to segregate them. In Norway both systems have been followed, the report states, and the number of lepers has dropped from 3,000 to 285 in fifty-seven years. But analysis of these statistics shows that the decline closely parallels the increasing numbers of cases that were isolated. In Norway, besides, the central government has control over the whole country, and uniform measures of surveillance could be applied. The report emphasizes that conditions in Brazil are very different from this, no uniformity in the twenty different states of Brazil being pos-

sible under existing conditions. Hence segregation is the only practicable system for prophylaxis of leprosy. But the committee urges that the leper colonies should be attractive and easy of access to the lepers' friends.

Hemorrhagic Purpura.—Cardoso relates that the first of his two recent patients with hemorrhagic purpura was a man of 31. This is the only case in his experience with recovery after hematuria. The second case was in an infant, 6 days old, and the child died in a week, notwithstanding energetic treatment. Other members of the family showed signs of inherited syphilis, and specific treatment had been pushed but the child succumbed before its effect had had time to become manifest.

*Urinary Calculi. J. B. Ascanio-Rodríguez.—p. 293.

*Syphilitic Disease of the Heart. Ignacio Benítez.—p. 301.

Acute Pulmonary Edema. B. Perdomo Hurtado.—p. 308.

*Ocular Hyperemia and Menstruation. J. M. Espino.—p. 311.

Urine Factors in Pathogenesis of Calculi.—Ascanio-Rodríguez insists that urinary calculi require certain conditions for their development: The urine has to be alkaline before phosphate concretions can form; and it has to be extremely acid for urate concretions. He refers further to the hyperacidity of the soil and the hypo-acidity of the excretions in the uric acid diathesis, while the reverse is the rule in conditions such as scrofula. By modifying the reaction of the urine, therefore, conditions are brought about which directly favor or annul the tendency to formation of concretions, and aid in the dissolving of the concretions already formed. Analysis of the urine is the guide, and will warn of incipient lithiasis in time to ward it off. He gives no details of treatment along the lines he thus suggests.

Syphilitic Disease of the Heart.—Benítez describes the pathologic anatomy of syphilitic lesions in the heart, saying that the coronaries usually feel the effect first.

Ocular Hyperemia and Menstruation.—Espino describes the case of a healthy married woman of 28 who for the last three years has had severe congestion in one or both eyes just preceding and during her menstrual periods and never at any other time. There is slight photophobia but no pain, secretion or lachrimation.

*Mixed Tumors of Salivary Glands. Elpidio Stincer.—p. 477.

*Asthma in Child. M. A. de Villiers.—p. 481.

Tumors of Salivary Glands.—Elpidio Stincer reviews his experience with 9 mixed tumors of the salivary glands. In 4 there was sarcomatous tissue and one was of endothelial nature mostly; 2 were adenocarcinomas. All but 2 were in the parotid gland, and all were on the right side. The duration of three to thirteen years suggests the mixed type; cases of ten, twenty and thirty years' standing have been recorded. These tumors are generally encapsulated and recurrence need not be feared when removed early.

Asthma in Child.—The girl of 9 was of the lymphatic temperament, but healthy, and she had a severe attack of asthma for the first time last July. It lasted for two days and then subsided without leaving a trace. In August, after exposure to rain, intense asthma developed, with severe cardiovascular complications, weak and rapid pulse, cyanosis and extreme prostration. Epinephrin, camphorated oil, revulsion with mustard baths, etc., finally reduced the severity of the symptoms, and the temperature which had gone up during the day returned to normal and by the third day from the exposure there were no further symptoms. The child has had no return of them since.

Revista de Medicina y Cirugía Prácticas, Madrid

October, 1919, 125, Nos. 1573-1576

*Salpingitis and Neoplasms with Prolapse of the Uterus. Alvaro Esquerdo.—p. 5.

*Technic for Administration of Digitalis. A. Espina.—p. 81. Conc'n.

*Progressive Muscular Atrophy. R. del Valle y Aldabalde.—p. 122.

Salpingitis and Neoplasms with Prolapse of the Uterus.—Alvaro Esquerdo has had two cases in which gangrene developed in the prolapsed uterus and part of the vaginal walls; in one of the cases he succeeded in arresting the gangrene, with recovery, but the other woman died from peritonitis. In three other cases the prolapse was strangulated, but reduction proved possible in time. He warns against attempting a vaginal operation if there is any question of complicating salpingitis or tumor. For one reason, because removing the uterus would open the way for hernia of intestines. Another reason against it is the risk of hemorrhage from the inflamed and congested tissues. A third reason is the danger of cutting the bladder, rectum, or ureters as these organs are pulled out of their normal places. The suppurating adnexa can be drained by posterior colpotomy, but conditions otherwise should be corrected by way of the abdomen. Subtotal hysterectomy is preferable for obvious reasons, he reiterates.

Digitalis.—In this study of the technic for administering digitalis, Espina remarks that the most difficult point is to know when and how to stop it. The urine and the pulse form the gage for this. He advises to give digitalis only with the finger on the pulse, the ear over the heart, and watching the patient's aspect.

Progressive Muscular Atrophy.—Del Valle reports pronounced improvement in the case of progressive muscular atrophy in a man of 46 under electricity and hot sand baths twice a day. The best results were noted when the sand bath just preceded the faradization. The impotence of the hands from the muscular atrophy retrogressed under this mixed treatment in five months to such a degree that further treatment was not required. He was a workman, and the first symptoms had been noted three years before. Repeated chilling of the hands was the only causal factor that could be discovered, and this suggested the advisability of the hot sand baths. The advantages of the sand bath are the unusually high temperature that can be used, the fact that perspiration can proceed unhindered, and that there is no maceration of the skin. No benefit was apparent from a course of strychnin, and it was abandoned.

*Gold Reaction in General Paralysis. A. Prunell.—p. 620.

*Herpes Zoster. J. Servetti Larraya.—p. 635.

*Slow Pulse with Appendicitis. Carlos Stajano.—p. 640.

*Temporary Tubal Sterilization. Augusto Turenne.—p. 645.

Gouty Rheumatism.—Butler's patient is a well-to-do man of 55 with rheumatism in the shoulders which yielded to potassium iodid and dieting. For some years there had been pains in the sacrum and the roentgen rays revealed a huge tophus. There were also small tophi in other bones and joints, confirming the case as one of gouty rheumatism. In true rheumatism the condensing osteitis casts a heavier shadow than normal, while in gouty rheumatism the shadow of the tophi is much lighter than usual, the urates which have taken the place of the calcium salts being comparatively translucent. The apparent loss of substance in the sacrum measured 6.5 by 7 cm.

Puerperal Thrombophlebitis.—Estapé and Collazo comment on the difference in the prognosis according as the thrombophlebitis is of septic or aseptic nature. All parturients should be systematically examined for any rise in the rectal temperature and for any signs of phlebitis in the genital sphere, while the pulse should be taken every eight hours. When the rectal temperature runs up in waves but no cord can be palpated in the pelvis, although the pulse shows steps of acceleration and there are chills and other symptoms of thrombophlebitis and even of phlegmasia alba dolens, the phlebitis is probably located in muscle or the viscera at some distance. When the cord can be palpated in addition, septic puerperal thrombophlebitis is probable and the outlook is grave on account of complications unless a ligature is applied

early. An aseptic phlebitis does not have the rise in the rectal temperature although the pelvic cord, the pulse, varices and the atony of the uterus are otherwise the same, but the prognosis is benign. The progressive septic form has, in addition, slight edema and formication in the members. The outlook is grave with this, even after the ligature. The complications may be biologic from infection of the thrombus, or mechanical from its extension or fragmentation. They give the details of three cases; in two there was double phlegmasia alba dolens and one of these women was left with complete functional impotence of the legs. The septic uteropelvic thrombophlebitis was confirmed by the laparotomy, and ligation of the hypogastric vein on both sides and also of the utero-ovarian vein on the left side arrested the process. The first symptoms had been noted twenty-two days before the operation, but there was no fever for the first ten days, and then only transiently.

Rupture of Uterus at Term.—The rupture was spontaneous and longitudinal but it caused no characteristic symptoms and was only casually discovered. Immediate abdominal cesarean section and subtotal hysterectomy were followed by prompt recovery.

The Colloidal Gold Reaction in the Spinal Fluid.—Prunell analyzes the findings with Lange's reaction in forty-five cases. They were constantly negative in normal cerebrospinal fluid and also in nervous pathologic conditions other than syphilitic, while with general paresis the curve was constantly between 555555 and 455431.

Electric Treatment of Herpes Zoster.—Servetti reports the prompt attenuation of the pain and the disappearance of the eruption in the two cases in which he applied the galvanic current to the region. The positive electrode was placed on the vesicles of the eruption and the negative electrode over the emerging point of the posterior roots of the fourth and fifth intercostal nerves of the right side, increasing from ten to twenty milliamperes, the sitting lasting from twenty-five to thirty minutes daily. The pain was relieved by the first sitting, and the cure was complete by the fifth.

Slow Pulse and Appendicitis.—Stajano emphasizes that in children a slow pulse is a favorable sign as it does not appear until the process is retrogressing. It is followed by progressive improvement. It is rarely observed in adults, and its significance varies in adults.

Temporary Tubal Sterilization.—Turenne has operated in four cases by suturing the fimbriated extremity of the fallopian tube in a bed made for it through an incision 15 or 20 mm. long in the anterior layer of the broad ligament. This leaves the tube freely movable, and does not kink it. Conception can be rendered possible again at any time by a short incision in the tube lower down, and suturing the lips of the incision to the ovary.

- *Pregnancy Asthma. M. Ruibal Salaberry.—p. 278.
- *Influenza. Luis Lancelotti.—p. 281.

Bacteriology of Influenza.—Destéfano and Tobias conclude their seventeen page review of the data on record to date by accepting a filtrable virus as the primary cause of influenza.

Cyst in the Iris.—The spontaneous serous cyst in the iris in the case of which an illustrated description is given subsided under bipolar electrolysis.

Atresia of the Vagina.—Rojas explains that atresia of the vagina and internal genital organs generally includes lack of the ovaries also. When there is atresia of the vagina and a rudimentary uterus, there is usually a tendency to menstruation. If the uterus and ovaries are well developed, along with atresia of the vagina, retention of the menstrual flow causes severe disturbances. When an artificial vagina

has to be provided, the Baldwin or Abbott method seems preferable as a rule.

Pregnancy Asthma.—Ruibal Salaberry has encountered four cases of pregnancy asthma during the last four years, and he found albumin in the urine and no chlorids as special features of this type of asthma. The farther advanced the pregnancy, the severer the asthma, the greater the retention of chlorids and the more intense the albuminuria and the edema, and the woman weighs more to correspond. The asthma is thus a manifestation of toxic chlorid retention. Treatment to promote elimination of chlorids and prevent their ingestion—that is, theobromin and restriction to water and milk—soon arrests the tendency to asthma.

Bone Formation in Laparotomy Incision.—Gutiérrez removed the gallbladder through a transverse incision in July, 1917. In May, 1918, the woman returned, complaining of a bulging of the laparotomy cicatrix and some pain in it. The old cicatrix was incised and a bony formation extracted, corresponding to the shape of the cicatrix, with no contact with the ribs. The microscope showed the structure of true bone; the aspect was much like that of a rib.

Tuberculin Treatment of Tuberculosis.—Gómez Alvarez reiterates the advantages of extreme dilution of tuberculin for systematic treatment of tuberculosis. He calls this extremely diluted tuberculin "bacillin," and relates his surprise when infinitely better results were obtained with a much weaker dilution than the one he had been using. Further experience, he declares, and study of the classified card records of his cases have confirmed more and more the correctness of his premises and his methods.

Archiv für Kinderheilkunde, Stuttgart

Nov. 30, 1918, 67, No. 1-2

- *Acute Lymphatic Leukemia in Infants. E. Tancré.—p. 7.
- *The Weight and the Resistance to Infection. F. Stickler.—p. 15.
- Congenital Atresia of the Isthmus of the Aorta and Mitral Stenosis in Girl of Five. H. Bergmann.—p. 44.
- *Individual Isolation as Factor in Prophylaxis of Infections in Institutions. D. A. Sokolow.—p. 56.

Leukemia in Infant.—The acute lymphatic leukemia had developed in an apparently healthy male infant after a suppurating process at the umbilicus at the age of one month. Necropsy at 4 months revealed intense lymphoid proliferation in all the organs and that all the glands were slightly enlarged although they could not be palpated during life. The skin never showed ecchymoses and suffusions and the case was exceptional further in that no leukocytes but lymphocytes were found in the blood.

Weight and Resistance to Infection.—Stickler analyzes 200 cases of scarlet fever and 500 of diphtheria, recording the severity of the infection and the child's weight in proportion to its height and to the standard weight for its age. The findings were in favor of the thin children, the course and outcome of the diseases being on the whole somewhat more favorable in the children below the average weight.

Individual Isolation in Hospitals.—This long and illustrated article by Sokolow was read at the All-Russian Pediatric Congress in 1912.

Correspondenz-Blatt für Schweizer Aerzte, Basel

Nov. 6, 1919, 49, No. 45

- *Sudden Death in Heart Disease. Walter Frey.—p. 1689.
- *Lethargic Encephalitis in Switzerland. G. Müller-Bergalonne.—p. 1695.
- *Raying after Removal of Cancers. Max Steiger.—p. 1704.

Sudden Death in Heart Disease.—Frey disputes Hering's assertion that auricular fibrillation is the cause of sudden death. This, he asserts, is incapable of causing the sudden arrest of both heart action and respiration which is characteristic of this "seconds-heart death," as it is called when only a few seconds elapse between the first symptoms and

death. He presents arguments to sustain the assumption of a nervous shock affecting functionally the closely connected centers of respiration and circulation. With heart disease, the regulating mechanism for these centers is in an abnormally excitable state, so that there is an excessive reaction to even normal stimuli. He describes how a stimulus emanating from the heart itself may act on these centers, and thus arrest by reflex action both the heart and respiratory functioning. Intracardial increase in pressure may be an important factor in this. Physical exertion is frequently the determining factor; or sudden failure of the contracting power. The latter is witnessed in the sudden death in diphtheria, the relaxation of the heart muscle setting up the reflex inhibition of heart and respiration.

Lethargic Encephalitis.—The case described is said to be the first one of epidemic lethargic encephalitis encountered in Switzerland, but four others have been observed since in the same town (Geneva). The patient was a woman of 28 and the symptoms indicated tuberculous meningitis at first. Necropsy revealed a primary microscopic acute poli-encephalitis.

Raying After Removal of Cancer.—Steiger reviews the experiences with cancer at the university clinic for women's diseases at Bern before and during the four years since roentgen exposures after removal of the cancer have been the routine procedure. In a series of 148 cases 1908-1913, only 13 per cent. have been practically cured to date. The survival averaged 12.2 months but the corresponding survivals in the later, rayed series averaged 18.3 months. Fully 90 per cent. of the nonrayed series died and only 4.3 per cent. of the rayed in corresponding periods of time. These and other data confirm the decidedly favorable influence of roentgen exposures after removal of the cancer, and as the technic is being improved, constantly better results are being realized.

- *Osteogenous Osteomyelitis in Children. F. Siebenmann.—p. 1737.
*The Declining Birth Rate. H. Hunziker.—p. 1741.

Fulminant Osteogenous Osteomyelitis in Children.—Siebenmann refers to the acute osteogenous osteomyelitis of the temporal bone or other bones of the skull, of which he has encountered seven cases, all but one in girls. There had been preceding chronic otitis media in only one case. The onset is stormy in the midst of apparent health or infectious sore throat or bronchitis, with intense earache and high fever, continuous or of a pyemic type. All his seven patients died between the ninth and sixteenth days. Even an early operation in such cases shows places where the destructive process seems to have skipped these points to attack points beyond, but this does not imply a blood-borne origin. The skeleton outside of the immediate region was not involved. Operative measures in his cases were unable to ward off the fatal pyemia, although the focus was excised apparently into sound tissue the fourth or fifth up to the ninth day.

The Declining Birth Rate.—Hunziker's charts show that the birth rate in Switzerland has long been gradually declining, but the drop has been steeper since 1914. Even in 1911, only Spain, Belgium, Ireland, and France had a smaller excess of births over deaths among the twenty-one states in Europe. In Basel the birth rate per thousand was 18.37 in 1914 but only 12.7 in 1917. Hunziker comments that the gravest danger from the declining birth rate is that birth control is not practiced by the feeble-minded, the drinkers, paupers and other inferior elements. They breed out of all proportion to the better elements of society. He adds that Greece and Rome owe their fall to the lack of production of new generations of members for the leading classes.

*Influence of Fat-Poor Food on Cholelithiasis. Kirschner.—p. 300; Idem. W. N. Clemm.—p. 302.

Malaria with Intestinal Complication.—Wörner reports considerable experimental and clinical experiences which demonstrated that the elimination of quinin by way of the feces continues for three or four days almost the same whether the intestines are sound or there is dysentery. Hence with dysentery the quinin can be given by the mouth if desired. But with profuse diarrhea, suggesting disease of the small intestine, there seems to be an exaggerated elimination of the quinin through the stools. Consequently parenteral injection of the quinin is preferable under these conditions. The dose of quinin in the cases ranged from 1.2 to 2 gm., given in half gram doses at hourly intervals.

Fat-Poor Diet Invites Gallstone Disease.—Clemm is convinced that a diet with plenty of fat is less liable to be accompanied with gallstones than a fat-poor diet. He remarks that cholelithiasis seems to have become much more prevalent in the last two years.

Intraspinal Treatment Exclusive of Serotherapy.—Neumann reviews the present status of intralumbar therapy with physiologic salines, tuberculin, magnesium sulphate, silver salts and ethyl-hydrocuprein. The consensus of opinion in regard to the latter, she says, seems to be favorable. No untoward by-effects were observed in the experience of several, but Landsberger had paralysis of the bladder develop in several of his cases which, although transient, compelled the suspension of the treatment. The indications for it were pneumococcus and meningococcus meningitis.

Treatment of Sterility.—Sippel describes various measures that might be used for correction of mechanical obstacles to the passage of the ovum or spermatozoa into the uterus. A suppurating catarrhal condition in the cervix may impede conception, and disease of the endometrium may prevent the embedding of the ovum. When the fimbriated extremity of the tube has become obstructed, he advises to resect the distal end of the tube and overcast the raw edges with fine catgut to hold the lumen open. Unsuccessful attempts at artificial sterilization have demonstrated that conception is possible with only a fragment of the tube. In conclusion he discusses artificial fertilization, and what he calls war pregnancies, that is, when women who have long lived in sterile wedlock conceive when their soldier husband returns home on a furlough after a long absence. Among the factors which might explain this are the thinness of the women from the war diet restrictions and the chance for any genital inflammatory processes to have healed. We must remember, however, that even when one element is corrected, there may be other inhibiting factors at work.

Puncture of the Brain.—Paetsch comments on the fact that so few think of puncturing the brain for diagnostic and still fewer for therapeutic purposes. He insists that it is much less of an operation to puncture the brain than it is to trephine the skull, and he reports several cases to illustrate the great therapeutic value of the simple procedure. In one case puncture released 35 c.c. of fluid blood and the paresis of the left arm and leg retrogressed. The puncture had been made between the arm and leg centers and the puncture was repeated ten days later at the same point on account of the persistence of headache, choked disk and pulse of 50 or 60. About 36 c.c. of thick blood containing methemoglobin was evacuated and there has been no further trouble since. A tendency to unconsciousness, pulse 40, and frontal headache had been the only symptoms at first, coming on two weeks after a fall. In another case a girl fell down stairs and was unconscious for five days notwithstanding early puncture of the brain. Then the motor region in the other hemisphere was punctured and 56 c.c. of old fluid blood was evacuated from beneath the dura. The condition improved but recovery was not complete until after

another puncture which released merely cerebral fluid. No local symptoms had been evident at any time and the surgeon would not have known where to trephine, while the puncture answered every purpose and undoubtedly saved the child's life. One man presented the symptoms of a brain tumor in 1903 but it could not be localized. Puncture of the right and left frontal lobes and the right cerebellum gave no relief, but puncture of the left cerebellum released 40 c.c. of an amber fluid and all disturbances subsided. They returned again after a few months and again after intervals up to eight years, but each time puncture in the same region seemed to drain the presumed cyst, and all the disturbances disappeared. Paetsch has had two similar cases in wounded soldiers in which each time recovery followed puncture of the brain.

*Cancer of the Clitoris. R. Ederle.—p. 110.

*Osteomalacia. E. Scipiades.—p. 156.

Genesis of Symptoms of "Pregnancy Kidney."—Eckelt reiterates that tests of kidney functioning have conclusively demonstrated that there is no insufficiency of the kidneys with the congested kidney of the albuminuria of pregnancy, and hence its cause must be sought elsewhere than in the kidneys. The dropsy, the hypertony and the visual disturbances which we encounter in the pregnant are to be regarded as independent morbid phenomena for which the gestation process is responsible. They are pregnancy toxicoses like eclampsia, albuminuria, uncontrollable vomiting, etc. In none of the cases on record of the alleged evolution of pregnancy kidney into chronic nephritis is the proof convincing, preexisting kidney disease excluded, or such after intercurrent infectious sore throat; the course traced continuously from the pregnancy kidney to the chronic nephritis, and, thirdly, the diagnosis of nephritis not based merely on the albuminuria but on reliable functional tests. The frequent occurrence of albuminuria in the course of pregnancy testifies that the kidney is often subjected to great strain, and it is possible that repeated damage might in time entail chronic nephritis. With pregnancy kidney no benefit was derived from restriction of water and of salt in the cases described in detail. Any benefit from the restrictions was evidently due to the bed rest enforced along with them. Some toxic change in the structure of the vessels is manifestly the cause of the dropsy and of the higher blood pressure and this, also, is favorably modified by the bed rest. The experiences he relates confirm that even extreme edema and high blood pressure should never decide as to whether the pregnancy should be interrupted or not. He has witnessed both very pronounced borne without harm for mother and child. Even disturbance in vision is not an absolute indication for emptying the uterus. Only when it develops a long time before term is there danger, as a rule, of irreparable damage to the eyes. When it occurs just before delivery, expectant treatment, particularly under supervision of an ophthalmologist, is indicated. In two of the cases he reports, severe retinal changes retrogressed completely after delivery. It seems wisest, on the whole, he adds, with normal renal functioning to accept the eye findings as the guide whether to interrupt the pregnancy or not. If the functional tests, albuminuria, the dilution and concentration properties of the kidney, the residual nitrogen, and the molecular concentration of the blood show reduced functional capacity in the kidneys, then the pregnancy should be interrupted, regardless of whether the kidney is suffering from a pregnancy toxicosis or an actual nephritis.

Contracted Pelvis at the Berlin Charité.—Heyn analyzes the experiences with 311 primiparae with contracted pelvis and 317 multiparae. The mortality was 1.7 per cent. among the mothers and 11.6 per cent. among the children. The out-

come among the women taken into the hospital a little before term was almost as favorable as in normal cases. A further advantage of this is that it gives an opportunity to study such cases under safe conditions.

Toxic Meningitis After Intraspinal Anesthesia.—Bracht compares the necropsy findings in one case and the clinical findings in two others with similar cases on record. The microscope confirmed the aseptic nature of the meningitis; death occurred from pulmonary embolism. The symptoms closely resemble those of any meningitis, and delirium alternates with somnolency. The temperature is no criterion. The fluid was clear at first but later opalescent or strongly turbid. The procain-epinephrin solution had been boiled up the night before, and it had probably altered by standing till next day. In conclusion he urges research to distinguish between the symptoms due to irritation of the meninges and the symptoms from direct injury of the nerve substance itself. This might reveal which of the elements of the anesthetic are responsible for the different injuries and permit their elimination.

Diabetes and Pregnancy.—Reinhardt concludes from the three cases he reports and review of the literature that the pregnancy does not necessarily aggravate the diabetes during the first two thirds. But very often the uterus becomes dangerously distended with amniotic fluid, and a large proportion of the fetuses die. After the delivery, the puerperium proceeded approximately normally in his three cases. The diabetes, however, seemed to become graver from the fact of the pregnancy, although it was not allowed to go to term. The pregnancy in itself is a strain for the diabetogenous organs, especially the liver, and acidosis and coma are menacing even after the most cautious induced delivery. The danger of acidosis grows greater the longer the pregnancy lasts, and when coma has once developed we cannot control it. Hence he advises not to wait too long before emptying the uterus.

Primary Carcinoma of the Clitoris.—The carcinoma had developed on the basis of a papilloma of fifteen years' standing, and it was eradicated with the cauterization. Ederle reviews the publications on these growths, showing a percentage of about 16 per cent. clitoris cancers among 677 vulvar cancers. Ederle has compiled a total of 182 cases of clitoris cancers; in 64 they were restricted exclusively to the clitoris. Among the patients 0.3 per cent. were under 20 and 4.4 per cent. between 20 and 30. Pruritus is usually the first symptom. He compares the glandular involvement, etc., with those of other cancers in the genital organs, and remarks that roentgen therapy does not seem to offer any prospects of success with vulvar cancers.

Osteomalacia.—Scipiades devotes seventy pages to this account of his experimental and clinical research on internal secretions as affecting osteomalacia. It has convinced him that the thymus is responsible for the processes which induce human malacia. All influences which induce an intensive accidental pathologic involution of the thymus gland entail osteomalacia, especially when followed by a rapid succession of pregnancies without corresponding pauses for lactation and involution of the thymus. The thymus etiology does not conflict with but throws more light on the data already accumulated in regard to osteomalacia.

*Relations between Pregnancy and Pulmonary Tuberculosis. E. Lindhagen.—p. 897.

Relations Between Pregnancy and Pulmonary Tuberculosis.—Lindhagen has witnessed in three cases the whipping up of pulmonary tuberculosis into a fulminant form after a childbirth, as he describes in detail. He also cites similar experiences published by veterinarians in regard to goats and other domestic animals. The curves from his three cases show the almost immediate rise of the temperature after the delivery, and the close succession of peaks to the fatal outcome in one, two and six months.

SELECTIVE BACTERIOSTASIS IN THE TREATMENT OF INFECTIONS WITH GENTIAN VIOLET

JOHN W. CHURCHMAN, M.D.
NEW YORK

The selective bacteriostatic property of gentian violet, which has been the subject of various publications¹ since 1912, has been studied during the past three years with particular reference to the possible application of the laboratory findings to the treatment of infections. In recent publications in THE JOURNAL,² the results of the treatment of acute infections of the knee joint, by the method of lavage and staining, without operation, were described. These results were sufficiently encouraging to warrant an extension of the studies, and this is now being undertaken with a more abundant material than was at my disposal at the time of the earlier publications.

My purpose in this paper is to report the results of attempts to apply the selective bacteriostatic power of gentian violet to the treatment of infected wounds.³ The activity of the dye is described as bacteriostasis, the dye is called a bacteriostat, and its property is referred to as bacteriostatic, partly because these words, unlike the monstrous "bactericide" and "bactericidal," are etymologically correct; but more particularly because they describe with nice accuracy the action of the dye. It is certainly true of gentian violet (careful study would doubtless prove it also true of other so-called bactericides) that apparent death of organisms, following exposure to the dye, may turn out, on careful study, to be only delay of growth.

Attention was called to this fact, and to its possible theoretical significance, in a brief note on a series of experiments in which stained *B. anthracis* was injected into the circulation.⁴ Furthermore, the fact that the power of this dye (or of any other agent used in the

treatment of infection) to prevent growth, may be of equal therapeutic importance with its power to kill organisms is recognized when the dye is described as a bacteriostat; and the fact is of sufficient importance to demand recognition. None the less, in the large amount of literature on the treatment of infections with anilin dyes which has appeared since my first publication in 1912, this important feature of bacteriostasis has been consistently overlooked.

The fact that the power of a therapeutic agent to prevent the growth of organisms may be quite as important as its power to "kill" organisms is one reason the more (a dozen others could be cited) why the custom of estimating the value of a "bactericidal" agent by its phenol coefficient alone is a pernicious one. Such a growth-preventing, or bacteriostatic, property gentian violet possesses, even in very high dilutions. At least it possesses this power, in high dilutions, when the test is made in vitro; but it would be unwise to expect that this sharp selective activity would be exhibited in as clear cut a fashion in wounds as in the test tube. Numerous considerations warned against the folly of such a supposition; and the results in the study on wounds carried out at the Walter Reed Hospital were, indeed, less concise and clear cut than they had been with test tube experiments. None the less they paralleled these; and it was particularly interesting to find that in wounds, as in the test tube, it was the gram-negative organisms which were least affected by the dye. In Figs. 2 and 3, the organism persisting in wounds which had been treated with gentian violet has been stroked at each side of a gentian violet plate, and a stroke of *Staphylococcus aureus* has been made at the center, for contrast. The persisting organism is seen to behave as gram-negative organisms do; and it proved, indeed, to be *B. coli*. The behavior of the gram-positive *B. diphtheriae*, on the other hand, toward gentian violet is shown in Figure 1; and treatment of the wounds, as will be described later, was completely efficacious in ridding them of this organism.

In attempting to apply gentian violet to the treatment of infected wounds, I had in mind the difficulty which had first to be contended with in attempting to use the dye in the treatment of infected joints: the absurdity, that is, of applying this, or any other, bacteriostatic agent to an infected surface with the hope of reaching the organisms concerned, unless this surface had first been mechanically cleansed. When a substance is used which can be as plainly seen as gentian violet, this absurdity is apparent; for the dye is seen staining the secretions and fibrinous products of inflammation, which protect from the action of the dye (as effectively as a layer of grease would do) the

3. Ample opportunity for this study was given by the kindness of Surgeon-General Ireland, through whom laboratory facilities and free access to the rich material of the Walter Reed Hospital were provided for the purpose. It is a pleasure to acknowledge with gratitude the kind assistance of the commanding officer, Colonel Glennan, and of the chief of the surgical service, Col. William Keller.

4. Transactions, Tenth Annual Meeting, National Association for the Study and Prevention of Tuberculosis.

underlying granulations in which lie the organisms concerned. In the case of the joints, an apparatus has been devised whereby this preliminary cleansing can be well done;⁵ in the case of wounds it was necessary to incorporate mechanical cleansing in the technic of the daily dressings. This was done in a painstaking way. After the usual cleansing of the skin surrounding the wound, the granulations themselves were gently washed with neutral soap, dried by mopping, and then flooded with hydrogen peroxid. This was repeated until the granulations were left naked. Minute pockets were cleaned, much as a dentist cleans the pockets in the gums, and special attention was given to the space just under the skin edge at the junction of skin and granulations where bacteria and secretions are likely to accumulate.

The cleansed granulations were dried by mopping with gauze, and were then painted with a saturated aqueous solution of gentian violet. The first coat was allowed to dry and a second coat applied. This was also allowed to dry, and a dry dressing applied.

Two types of wound were treated in this manner: amputation stumps that had become diphtheria carriers, and amputation stumps with ordinary infection.

Fig. 1.—Effect of gentian violet on *B. diphtheriae*: A divided gentian violet plate, the upper half of which contains gentian violet agar, and the lower half plain agar. The two lateral streaks (*D, D*) are of *B. diphtheriae*, and between them, for contrast, is a stroke of *B. coli* (*C*). *B. coli* grows equally well on the two portions of the plate, while *B. diphtheriae* fails to grow either on the gentian violet agar or anywhere near it.

Fig. 2.—Persistence of a gram-negative organism in a wound treated with gentian violet: The organism obtained from the wound (*B. coli*) has been stroked across the plate at the sides (*C, C*) and grows equally well on the gentian violet agar and on the plain agar. At the center (*A*) the plate has been stroked with *M. aureus*, which fails to grow on the gentian violet agar.

Fig. 3.—Persistence of a gram-negative organism in an empyema sinus treated with gentian violet: The organism obtained from the wound has been stroked across the plate at the sides (*C, C*); it is *B. coli* and grows equally well on the gentian violet agar and the plain agar. Between these two strokes (*A*) the plate has been stroked with *M. aureus*; this organism fails to grow on the gentian violet agar.

I. AMPUTATION STUMPS THAT HAVE BECOME DIPHThERIA CARRIERS

One of the most difficult problems to be dealt with at the Walter Reed Hospital was presented by patients with thigh amputations in which wound diphtheria had developed, and who had become diphtheria carriers. Two such patients had been isolated as carriers, one for four months and the other for several weeks; and from the wounds of both, cultures for *B. diphtheriae* had been constantly positive in spite of treatment with diphtheria antitoxin, surgical solution of chlorinated soda (Dakin's solution), argyrol crystals, tincture of iodine, chromic acid, silver nitrate, etc.

B. diphtheriae is gram positive and will not grow in mediums containing minute amounts of gentian violet (Fig. 1). It is killed by staining with the dye; and when observed in the living form in a hanging drop, it takes up the stain with great avidity, in contrast to the gram-negative organisms which—in a hanging drop—stain poorly and slowly.

These were sufficient reasons for assuming that it might kill this organism in wounds. Something might also be hoped for from its power of penetrating tissue;⁶ and the persistence of the dye (it remained apparently unchanged for periods varying from twenty-four to seventy-two hours and even longer) made it seem possible that even if the organisms were not actually stained, the continued presence of dye in the tissues might prevent growth, by a true bacteriostasis.

Both the cases treated were freed of *B. diphtheriae* in a short time. In order to determine positively that the organism was no longer present, the wounds were subjected to the most rigid scrutiny, for no dependence whatever can be placed, in these cases, on a single culture made from a surface smear. It seems probable that the organisms lie below the surface. For these reasons the wounds were regarded as sterile for *B. diphtheriae* only after the following technic had been observed:

(a) Four negative cultures were obtained on successive days, the cultures made twenty-four hours after the last previous treatment. Material for cultures was taken from the granulating surface and also from the blood serum obtained after rubbing the superficial granulations away.

(b) A fifth negative culture was obtained (in the manner just indicated, from the surface and from below the surface) after the wound had been left untouched for four days and the secretions allowed to accumulate on the surface.

(c) The cultures were made on Loeffler's medium; after twenty-four hours' incubation they were enriched by pouring glucose broth over the surface; and from this broth, after

6. Frequent reference has been made, in previous publications, to the fact that gentian violet, applied to the surface of a mucous membrane, penetrates to its depths. Great difficulty has been experienced in getting satisfactory sections, to study the exact depth of this penetration, as the dye is dispersed during the process of cutting even frozen sections, and this fact may lead to great error in interpreting the results. A technic has finally been devised which gives fairly satisfactory sections for microscopic study. The dye is applied to the living mucosa (by injection, for example, into the knee joint or the bladder), and the tissue is at once removed and thrown into Gram's solution, where it is left for two hours. The stained mucosa becomes a brownish black. The material is then put in 40 per cent. dilution of liquor formaldehydi, which, acting like an alcohol, restores the violet color, fixes the tissue, and dissolves out the excess of stain, but either removes not at all, or in the slightest degree, the stain that has been absorbed by the cells. After twenty-four hours' fixation, paraffin sections may be made in the usual manner. I have injected the living human knee joint by the technic described for the treatment of acute infections of the joints, and have made sections of the synovial membrane in the manner described, the leg having been amputated at the mid thigh for senile gangrene of the toes. These sections show beautifully the penetration of the dye (Figs. 4 and 5). The question will be more fully discussed in a subsequent publication.

5. Fully described in THE JOURNAL, April 13, 1918, p. 1047.

twenty-four hours' further incubation, transplants were again made on Loeffler's medium.

CASE 1.—N., Ward 26. A bad wound diphtheria, with membrane, about four months before. The membrane responded to antitoxin, but the patient had been a constant carrier ever since. Treatments with gentian violet were given daily from July 21 to July 25. Cultures were negative for *B. diphtheriae*, July 21, 23, 24, 25 and 29. There was a slight dermatitis in the skin about the wound, August 10, the wound having been left untouched for one week; cultures from the wound were negative for *B. diphtheriae*.

CASE 2.—Y., Ward 26. A constant carrier since July 2 (probably much longer, as the wound had given an unusual amount of trouble since it was first inflicted, months previously; but *B. diphtheriae* was first discovered July 2). Culture, July 26, was positive for *B. diphtheriae*. Treated with gentian violet, July 26, 27, 28 and 29. Culture, July 30, was positive for *B. diphtheriae*. Daily treatments were given from July 31 to August 9. Cultures, August 5, 7, 8, 9 and 12 were negative for *B. diphtheriae*. Transfer from the isolation ward was delayed by the appearance of an erysipelatoid rash in the upper thigh, 5 inches away from the wound, which appeared suddenly—with constitutional symptoms—and subsided in three days. Culture from the skin showed a coccus, but no *B. diphtheriae*. The patient was transferred to the open ward.

II. STERILIZATION OF STUMPS

No more difficult surgical problem occurs in a hospital like the Walter Reed—where the cases which still present problems are concentrated after the simpler ones have been sifted out—than that presented by unhealed or badly healed amputation stumps. In many of these cases, infection of the skin, soft parts and bone is present; in others, the skin flap left at the original amputation (often a guillotine) is deficient; in some, a persistent dermatitis or eczema has developed. All these conditions interfere with proper treatment, and militate against the success of the plastic operation necessary to provide the patient with a good weight-bearing stump.

The experience with the Dakin-Carrel technic in this type of case had not been particularly satisfactory. If the thigh stump was a short one it had not proved easy to apply the tubes; and when it was necessary to pull the skin flaps down with traction straps—as in most cases it was necessary—this difficulty was greatly increased. Worse than this, the dermatitis of the flaps, if present, was greatly aggravated by the Dakin solution, and in many instances it had to be abandoned for

this reason. In other cases, dermatitis not present in the beginning was incited by the Dakin solution; and even in patients who developed no visible skin lesion, complaints of severe burning of the skin were common.

It seemed possible that these difficulties might in part be avoided by attempting to sterilize the wounds with gentian violet. It was certain that this dye could be used without difficulty, by a simple technic, in combination with tension straps, with the use of which it would in no way interfere. It seemed certain, also, that the production of dermatitis need not be feared, as the dye would be applied to the granulations, where it was needed, rather than to the skin, where it was not. It proved, indeed, to be the fact that the progress of the most obstinate cases of dermatitis, already present, was greatly impeded by the use of the gentian violet technic.

Four cases of this sort were treated:

CASE 3.—Simple granulating wound at the end of a partially closed stump (midthigh).—Skin irritation had made the use of Dakin's solution impossible. It seemed probable that if the wound could be sterilized and the skin kept healthy, closure could be effected by adhesive plaster traction on the skin edges. Sterilization of this wound was accomplished without difficulty; the granulations became red and healthy, the skin normal; fairly rapid closure occurred, adhesive strap traction being used.

CASE 4.—Granulating wounds accompanied by marked dermatitis.—In D., Ward 74, the wound was an unhealed amputation of the thigh and consisted of a strip of dirty, grayish granulations, about 1.5 cm. wide, separating the edges of skin which, for a distance of about 5 cm. from the open wound was the site of a dermatitis of the most obstinate character. The skin was a light, brownish red, covered with dirty, superficial yellow

Fig. 4.—Synovial membrane knee joint injected with gentian violet, 1:1,000, just before a midthigh amputation (low power).

crusts, and touched, here and there, with very superficial ulcerations or abrasions of the top layers of epidermis. The patient suffered much from itching. Nothing that had been tried—and everything known had been tried—had done the slightest good. The indications, it seemed clear were to sterilize the granulations and thus do away with the infection which was causing their unhealthy appearance; and to do this without using any material likely to aggravate the skin condition. This was accomplished by careful mechanical cleansing of the whole field; the granulating surface was then painted with gentian violet and the skin well protected with paste. I received the distinct impression from this case and other cases that the relative sterility of the granulations produced by gentian violet, made the wound secretions less irritating to the skin and so less likely to produce or aggravate dermatitis. At any rate, the progress of this case was striking; the der-

matitis showed marked improvement in a short time; the appearance of the granulations became healthy, and epithelial growth from the skin edges, which had been stationary for weeks, began soon to close the wound in.

CASE 5.—*Granulating wounds accompanied by marked dermatitis.*—C, Ward 74. A case similar to the preceding. The

Fig. 5.—Synovial membrane, knee joint, injected with gentian violet, 1:1,000, just before a midhigh amputation (high power).

result of treatment with gentian violet was equally good, though less striking, as the dermatitis was less severe.

CASE 6.—*Granulating wound prepared for plastic closure.*—O., Ward 73, had had a long hospital career, with several operations, always complicated by sepsis. The amputation was at the midhigh. The skin would not tolerate Dakin's solution. A preliminary operation had recently been done, flaps prepared for closure, and the wound left wide open. Under gentian violet treatment, healthy granulations sprang up throughout the wound with great rapidity; these, in three weeks' time, had covered the bone end and reduced the wound to a space about $2\frac{1}{2}$ by $1\frac{1}{2}$ inches. It was impossible completely to sterilize it, a few colonies of a gram-negative bacillus (*B. coli*) always appearing in the plates (Fig. 2). August 15, however, a plastic closure was satisfactory except for about 1 inch at the center of the wound where infolding made good approximation impossible. Convalescence was uneventful. Healing occurred by first intention for about seven eighths of the wound. The central eighth (where approximation had been poor) separated about the sixth day for a length of about 1 inch. There was, no doubt, a mild infection in the subcutaneous tissues, but this did not interfere with healing by first intention throughout seven eighths of the wound.

GINGIVITIS DUE TO *B. FUSIFORMIS*

Reference was made in an earlier article⁷ to attempts made to use gentian violet in pyorrhea alveolaris, attempts which were attended with a considerable degree of success. The frequency and severity of ulcerative gingivitis (Vincent's angina) at the Walter Reed Hospital led to the adoption of the dye in the treatment of this disease. The cases were under the care of Major Butler of the dental department, in the excellent dental clinic under his charge. They were large in number and severe in degree; and their course was extremely satisfactory. It was Major Butler's distinct impression that the patients were materially benefited by the dye; but as it is difficult, if not impos-

sible, to control these cases bacteriologically, on account of the presence of the organism concerned in the normal mouth, the conclusions reached have only the value of clinical deductions. The penetration of the gum by the dye and its persistence are not open to dispute; and it certainly deserves more extensive trial in this and kindred types of gingivitis. Moreover, the *injection of the dye into the gums* (suggested in 1918⁷) should be studied, for this method of administration would allow the bacteriostatic action of the dye full play against organisms lying below the surface.

VAS PUNCTURE IN ACUTE GONORRHEA

WILLIAM T. BELFIELD, M.D.

CHICAGO

Current treatment of acute gonorrhea in the male recognizes the two conspicuous end-segments of the seminal duct, urethra and epididymis, but ignores the invisible, intermediate portion—vasa, ampullae and vesicles; yet these, combined, present a mucous surface nearly equal in area to that of the urethra (Figs. 1 and 2). The following departures from the current conception and therapy of acute gonorrhea are based on seven years' treatment of this intermediate segment:

1. The infection reaches the vesicles in more than half the cases during the acute stage, the first weeks. Such extension has been generally unrecognized because the symptoms induced by it have been commonly ascribed to acute prostatitis. The rôle of the vesicles is proved not merely by the detection of their pathologic condition by the trained finger in the rectum, but strikingly by the pronounced mitigation of symp-

Fig. 1.—Vasa, ampullae and vesicles filled with collargol solution by vasostomy; stiletted catheter in right ureter.

toms which follows immediately on filling them with a proper solution by way of the vasa. For example, a patient in the fourth week of gonorrhea, recently seen with Dr. L. B. Russell of Hoopeston, Ill., had for six days urinated painfully every thirty minutes to two hours night and day. Immediately after his vesicles were filled with 5 per cent. collargol solution, the pain

7. Footnote 2, first reference.

disappeared and the urinary intervals promptly increased to four, five and seven hours.

2. Acute gonorrheal vesiculitis, whether identified or not, has received merely symptomatic treatment combined with vaccines and foreign proteins. When with this aid the patient's immunizing powers fail to overcome the vesicle infection, he joins the great army of sufferers from gleet, chronic prostatitis, sexual

Fig. 2.—Vesicles, etc., filled with collargol solution. Since in chronic vesiculitis the diverticula of the vesicles here pictured are filled with semisolid masses, stripping of such vesicles usually fails to cure the chronic infection; even filling them with collargol occasionally fails.

derangements, and other recognized results of chronic vesiculitis.

3. The acutely infected vesicle, hitherto inaccessible to direct medication, is easily filled with a suitable solution by puncture of the vas. Moreover, a given infection is far more amenable to treatment in the vesicle than in the urethra, for two reasons: first, because the unstratified vesicular mucous membrane is entirely free from lacunae, follicles and glands, such as crowd the deeply stratified epithelium of the urethra; second, because the vesicle, like other sacs enclosed in unstriated muscle (stomach), automatically churns its contents. Since the color of the emitted semen proves the presence of collargol in the vesicles for weeks after they have been filled with it, we can understand that a single filling, followed by weeks of automatic mixing with the infecting agents unprotected by follicles, etc., may end acute infection of the vesicle, though producing far less effect in the urethra.

4. Medication of the vesicles does not, of course, cure the urethral infection, which requires independent treatment. A married man in the third week of gonorrhea showed bilateral vesiculitis; both vesicles were filled with collargol solution, and the urethra was treated by standard methods. At the end of a week the discharge had almost ceased, whereupon the patient discontinued treatment and resumed conjugal relations, using condoms. After nine days he returned with a profuse, purulent discharge, which was found to involve only the urethra (vesicles not infected), and which yielded to appropriate treatment of the urethra.

The prompt arrest of severe infection by this method was illustrated in a patient in the fifth week of gonorrhea, recently referred by Dr. George W. Hall of Chicago:

When first seen, this patient presented frequent and painful urination, severe perineal pain, creamy discharge with gonococci, tenderness of vesicles, and painful swelling of the right elbow and the right anterior tibial muscle; the temperature was 102.5. Both vesicles were filled with 6 per cent. collargol solution; two days later a thin discharge and subsiding swellings of the elbow and the leg were the only symptoms remaining. The discharge ceased after two weeks' treatment of the urethra and prostate; the arm and the leg were well within ten days after the vesicles were injected. A month after all treatment was discontinued, the emitted semen was found free from gonococci—the only proof of recovery, in my judgment, without which I decline to pronounce a patient cured.

This was the seventh case of acute gonorrheal rheumatism promptly cured by filling the vesicles with collargol. The first patient was operated on in St. Luke's Hospital, in February, 1913.

GONORRHEAL EPIDIDYMITIS

Since gonorrheal epididymitis is always an extension from the infected vesicle, and is prevented by timely medication of the vesicle, it should not occur in patients who obey instructions. Furthermore, the French operation, epididymotomy, leaves undisturbed the infection in the vesicle of which the epididymitis is a result; it mops up the floor but does not turn off the faucet. Twelve cases of recurrent infection in the incised epididymis have come to my notice. In one there had been three recurrences within five months after epididymotomy. In this and six other cases the trouble was ended by medicating the infected vesicle through the vas, which should, of course, be done whenever epididymotomy is performed. It is true that epididymotomy is not always followed by recurrence, and equally true that epididymitis without incision is not

Fig. 3.—Vasostomy: Through a scrotal incision three-fourths inch long the vas is lifted above the skin.

Fig. 4.—Vasostomy: The handle of an aneurysm needle is slipped under the vas, which is drawn tense and punctured with a bistoury point; a silkworm thread is passed into its lumen; the remaining steps are those described under vas puncture.

always followed by recurrence. But epididymotomy does not prevent recurrence, whereas injection of the vesicle does.

TECHNIC OF VAS PUNCTURE

The physician inexperienced in the surgery of the spermatic cord should first employ for the medication of the vesicle by way of the vas my original operation, described in textbooks on urology. For by this open operation the vas is lifted out of its sheath, in which it normally slides freely like a tendon, and is supported

above the skin before its minute lumen is opened (Figs. 3 and 4); hence the common pitfalls, notably the disastrous error of injecting the sheath of the vas instead of its lumen, are avoided through visual control.

Vas puncture, on the other hand, does not disturb the relations of the structures concerned, and hence requires familiarity with them. The vas must be immobilized under a tense scrotum. This can be done in many ways, for example, as a woman's embroidery is held tense between two embroidery hoops. The following is perhaps the simplest method:

After cleansing and anesthesia of the scrotum are secured, the vas is pressed by fingers against the lateral scrotal wall, and is fixed by tenaculum lock forceps (Braun's) whose points pierce the skin beneath the vas above the epididymis; a second pair of forceps encircles the vas similarly half an inch above the first. Gentle traction of the two instruments by an assistant renders tense the scrotum overlying the intervening vas (Fig. 5). The scrotum is then rested on any

the possible regurgitation of collargol out of the vas. Threaded in a fine hypodermic needle, a silkworm or waxed silk strand is carried into the lumen of the vas and out through the skin one-half inch above (Fig. 8); the needle is withdrawn, leaving the thread; its projecting ends are merely knotted, but are not tied together (important). This thread is a drain out of the vas and a guide for the blunt needle into the vas for subsequent injections, if needed; it should be withdrawn within five days.

Percutaneous puncture without using the knife appeals to the timid patient; but the security afforded by visual control of the puncture through incision far outweighs the disadvantage of the slight cut in the skin.

THE ADVANTAGES OF COLLARGOL AS A REMEDY

Collargol is used for medicating the acutely infected vesicles because of its advantages over all other remedies tried in my treatment of chronic vesiculitis by vasostomy.¹ Among its advantages are its penetrating

Fig. 5.—Vas puncture: The vas is immobilized under a tense scrotum by traction on tenaculum forceps; half-inch incision through scrotum and sheath to vas, whose coverings are drawn apart by snap forceps.

Fig. 6.—Vas puncture: Through puncture of the exposed vas with bistoury point a silkworm thread is passed into its lumen, and a blunt hypodermic needle is threaded over the silkworm toward the vas. (In this and the next illustration the tenaculum forceps, really remaining in position, are omitted to avoid confusion.)

Fig. 7.—Vas puncture: Needle has entered the vas, its shoulder closing the puncture; thread has been withdrawn and syringe connected.

convenient support. An incision one-half inch long or less exposes the vas. This is punctured with a bistoury point just enough to admit a fine silkworm thread, which should advance freely in its lumen. Or the puncture can be made with a hypodermic needle carrying the thread; but the bistoury point causes less injury and gives greater security. A blunt hypodermic or silver canaliculus needle is threaded over the silkworm into the vas (Fig. 6); the thread is withdrawn, and 10 c.c. of a 1:25,000 methylene blue solution are gently and slowly injected (Fig. 7). This should presently cause a desire to urinate; the urine passed should show the dye. If the color fails to appear in the urine, the procedure is faulty, and must be corrected or abandoned. The vas has been found occluded in more than 1 per cent. of my operations. The second vas is injected with fuchsin solution for contrast.

When the appearance of the dye in the urine has proved correct operation and patency of the seminal duct, 20 c.c. of 5 per cent. collargol solution are slowly injected, followed after two minutes' interval, by 1 c.c. of water, to minimize

power (unpleasantly illustrated in the kidneys), which probably explains its presence in the vesicles for weeks after injection; and its liquefying effect on semisolid, purulent masses. That collargol in 5 per cent. solution causes no damage to vas or vesicle, though certain other solutions used in the urethra do, was shown in an admirable experimental work by Lespinasse.² It seems also to be the agent generally used by those experienced in vasostomy.³

ONE UNTOWARD RESULT OCCASIONALLY FOLLOWING
VASOSTOMY

On the other hand, collargol is a factor in the only untoward result that ever follows vasostomy properly performed, namely, occlusion of the vas at the site of operation. That this is exceptional is indicated by the observation that four men, each of whom had only one testicle, all furnished normal semen after vasostomy. Such occlusion results partly from the extensive dissection, and partly from the regurgitation of collargol out of the vas into its sheath and surrounding structures, resulting in the formation of fibrous tissue. Both causes are eliminated by the technic of vas puncture already described, which should supersede vasostomy; but should such occlusion occur, it is remediable by a simple procedure, namely, excision of the occluded portion of the vas and union of the cut ends by a catgut or other suture.⁴

In working with the vas and its coverings I never use a sewing needle, but do my sewing with a fine hypodermic needle. This is made to pierce the vas and its surroundings wherever a stitch is desired; a silkworm or other thread is passed through the needle, which is then withdrawn, leaving the thread in the desired position with a minimum of injury to the delicate tissues involved (Fig. 8).

Fig. 8.—Vas puncture: After completion of injection, thread is placed and left as drain from the vas and guide for entrance of blunt needle for subsequent injections.

SUMMARY AND CONCLUSIONS

1. The traditional and still prevalent conception of acute gonorrhea as "specific urethritis" presents only a half truth; for in the majority of cases the disease becomes urethrovessiculitis within the first month.

2. Medication of the acutely infected vesicles and ampullae by way of the vasa with 5 per cent. collargol solution eliminates the infection from these otherwise inaccessible cavities. For this purpose vas puncture is preferable to the original operation, vasostomy.

3. The prompt arrest of the vesicular infection in the acute stage averts chronic vesiculitis with its manifold evils, eliminates epididymitis, and converts the hitherto refractory urethrovessiculitis into a urethritis only, with which we are well equipped to cope.

4. The seriocomic aphorism "Any man can make a date to get the gonorrhea; no man can make a date to get rid of it" reflects the futility of current treatment of the acute infection, futile chiefly because treatment is limited to one half of the infected area, the urethra; while in the other half, comprising vesicles and ampullae, the untreated infection persists undisturbed indefinitely. So long as pus produced in the vesicles appears at the meatus, the urethra is subjected to fresh—and futile—assaults.

In short, we treat acute gonorrhea as urethritis only; we are commonly dealing with urethrovessiculitis.

5. Before injecting the vesicle by way of the vas, the physician should master the technic either on the cadaver or through clinical observation; otherwise the patient should be referred to some one experienced in this work.

32 North State Street.

MODERN TREATMENT OF THE WEAK
FOOT

ARMITAGE WHITMAN, M.D.

NEW YORK

The subject of weak foot and its treatment has already been so thoroughly dealt with that those familiar with the subject may feel that anything now written can be nothing but repetition. To a certain extent this is true, yet there are aspects of the question that still need to be brought home to both the practitioner and the specialist.

Having only lately returned from an absence of nearly two years, I perhaps have somewhat altered my perspective, so that some things stand out more clearly than they otherwise would. I may not claim to cast any new light on an old subject, but I do state fairly that I regard it from a new angle.

To begin with, we have during the past two years given a large number of medical men, old and young, a grounding, or in case that word may seem too sanguine, an interest in orthopedic principles that they never had before. The medical officers in the Army who took the special orthopedic training have had emphasized, for probably the first time in their lives, posture, backs and feet in their direct relationship to efficiency. Efficiency is a much overworked word, one that is exceedingly objectionable to me. Let us say that it has been impressed on these observers that the man who walked with his back hollow and his toes turned out was unfit for the job that he had in hand. There could not have been a more favorable opportunity for the demonstration of the soundness of these principles, and for the change in public opinion that removed their supporters from the ranks of the faddists to those of the practical men. For almost the first time they were able to work with large bodies of men who were interested in what they had to say, and who looked to them to remove the stigma of being "unfit for active service." Incidentally, the surgeon experimenting for the first time in the application of these principles found the interest of his patients a spur to his mastery of the principles which he was trying to apply.

It is the combination of these two elements—interest on the part of both patient and physician—that is responsible for the present optimism displayed by certain members of the profession toward orthopedic practice in general. Many whose experience has been solely in cantonments on this side or in base hospitals or on splint teams in France are now deciding to take up orthopedics as a specialty. The public is interested and anticipatory. The word "orthopedics," though its meaning is by no means understood, has obtained wide circulation. It is with the idea of averting a certain disappointment that I am taking up the subject of the present day treatment of weak foot.

It may be said that there are at present two schools in the treatment of the weak and painful foot. The

Lydston, G. F.: *A New Method of Anastomosis of the Vas Deferens*,
J. A. M. A., 47: 169 (July 21) 1906.

first, and undoubtedly the largest, believes, or at any rate, practices, on the assumption that a sore foot is one of those ills to which man is inevitably heir, and that all that is needed in the way of treatment is relief of the patient's symptoms. This is accomplished in a variety of ways—by raising the inner border of the shoe, by applying a leather footplate, by putting bent pieces of metal in the shank of the shoe, or by applying various forms of metal sole plates. Little if any attention is given to the patient's attitude, or manner of standing or walking. If one questions the more learned followers of this school, they will answer that no patient is interested in his feet beyond the relief of the pain from which he may be suffering at the moment, and that any attempt to reform lifelong habits of gait, or style of shoe, is a waste of breath.

WEAK FOOT IN THE ARMY

The war has dealt a heavy blow at what we may call this "laissez-aller" school by demonstrating that the great majority of foot troubles could be cured without any apparatus whatever. There are two reasons for this. The first is that it was impossible to apply the apparatus. When I first joined the British Expeditionary Forces in May, 1917, as orthopedic surgeon to Base Hospital No. 2 (General Hospital No. 1, B. E. F.), I made a few attempts at manufacturing braces for the Tommies sent down the line because of disabilities of the foot. These, however, were fruitless, partly on account of the stupidity of the local French blacksmith, but mainly on account of the attitude of the British liaison officer, who said that even the most finished apparatus would be neglected or broken by the Tommy—neglected because he neglected everything outside his regular routine, or broken because he wanted an excuse for a rest. As they were in the habit of losing, breaking or pawning their false teeth for similar reasons, his point seemed well taken, and hundreds of otherwise fit men were shipped through to Blighty, there to be classified as P. B. (permanent base troops).

At the time I was transferred to the American Expeditionary Forces, in February, 1918, this attitude—that apparatus was impractical—seemed officially adopted by the orthopedic department of the American Expeditionary Forces. It, however, had gone the British one very much better in establishing a camp, or battalion, for soldiers rejected for active duty because of weak feet, weak backs, etc. There the feet were treated by raising the inner borders of the patient's heels and soles, and occasionally by applying a leather strap about the foot and ankle. Metatarsalgia was treated by a leather bar nailed across the sole behind the heads of the metatarsals. By carefully graded exercises alternated with periods of rest, and by constant supervision and rigid discipline, a very large proportion of these

soldiers were returned to combat duty, one of Colonel Goldthwaite's greatest triumphs.

The first demonstration that weak foot could be cured without apparatus thus being that apparatus under the existing circumstances was impractical—a decided forcing of the issue—we now come to the second. This was, as has already been suggested, military discipline plus morale and intelligence. The majority of the troops in question were willing and anxious to fight. Unless their feet were cured they could not. They therefore took the liveliest interest in their recovery. They were, in addition, under the direction of trained officers of more than ordinary experience, such as Major Z. B. Adams and Lieut.-Col. G. W. Hawley, and under them they were supervised by highly trained noncommissioned officers. They were properly shod and properly clothed, and their general condition was excellent. We have demonstrated the proposition that weak foot of this type can be cured without apparatus by taking highly trained athletes, eager for their task, under expert supervision and rigid military discipline.

WEAK FOOT IN CIVIL PRACTICE

Contrast the conditions which obtain in civil life. In hospital practice at least half of the patients are women, middle aged, hard working, fat housekeepers, on their feet all day long, 25 per cent. suffering also from varying degrees of varicose veins. The men are very much of the same class, middle aged street car conductors, policemen, bakers, cooks, and the like. There are comparatively few young men and girls and almost no children. As an illustration, the statistics of the Hospital for the Ruptured and Crippled during September, 1919, may be considered: Double weak foot: Males, 117; females, 146; under 15 years, 45; over 15 years, 218.

In private practice, men come because they are worried about a continual tired feeling, or a "strained foot" that does not get well, or because they have been told by the family physician that they have gout or rheumatism. Women come for the same reasons, and in addition there are a few who seek cosmetic improvement. Of late years, there have been a large, and fortunately increasing, number of children brought because of the ugly appearance of their feet, or awkward and peculiar gait.

To attempt the cure of these classes of patients is a widely different proposition from the military problem just described. The main obstacle, and the one first encountered, is indifference—indifference on the part of the patient and on the part of the physician. Most of the patients come expecting to be given some shoe that will afford immediate relief, and most of the physicians give treatment which may well be summed up in a reply given me by the chief of a large orthopedic clinic in a center of orthopedic teaching, when asked

Fig. 1.—The body weight, when the toes are turned out, falling on the inner border of the foot, as shown by the crease of the trousers.

how he treated these patients in hospital practice: "Anything to get rid of them."

We may assume, however, that men taking an interest in the subject for the first time, as our lately developed orthopedic practitioners are, will not be satisfied so lightly to dismiss the subject. We may assume also that an increasing number of patients will not be satisfied so lightly to be dismissed. I am strengthened in this opinion by the fact that I encounter in my hospital practice practically no patients who have not previously sought relief in some form of "orthopedic shoe," or by means of the various sole plates sold in drug stores. They will all state that these measures gave temporary relief, but that in a comparatively short time their symptoms returned. It is only rarely that they have been given any instruction in exercises, gait, posture, and the proper methods of using their feet. These facts may explain my skepticism in regard to the permanent effect of treatment by varied and non-descript forms of apparatus—apparatus applied for the relief of symptoms without aiming definitely at the original cause of the defect.

Except in rare cases of congenital flatfoot, and deformity as the result of accident, it may be safely stated that the underlying cause of weak foot is the attitude of eversion of the foot. To put it in the simplest possible way, the principal cause of weak foot is the persistent attitude of eversion, to which the commonest predisposition is the practice of standing and walking with the toes turned out. The effect of this attitude is to cause the body weight, transmitted downward through the lower extremities, to fall to the inner side of the foot instead of through its center. This attitude being established, it is only a question of time for the astragalus to begin rolling downward and forward off the os calcis, thereby pressing on the ligaments, causing pain, and ultimately deformity. The mechanism of this process is simplicity itself, and may be demonstrated by dropping a plumb line from the patella, noting where the weight falls when the feet are in the different attitudes. A well creased pair of trousers may be adapted to the same purpose, as in the accompanying illustrations.

Once this principle has been established, it remains only to correct the bad habit in the patient. Granted that this may be done by military discipline plus the desire of the patient to be cured, in civil practice we encounter two difficulties. The private patient is not sufficiently interested in his feet to devote to them the necessary amount of thought; and the hospital patient, who has to be cured during the course of the very occupation that may have caused his disability, has not the strength in his tired and overstretched muscles to maintain the attitude continuously. We therefore find it necessary in most cases to apply some form of support.

METHOD OF TREATMENT

The only apparatus hitherto devised which at the same time supports and attempts to correct the predisposing attitude is that of Dr. Whitman. It not only

"supports the arch," but also provides the lateral pressure which, as it were, nips the deformity in the bud. If a patient wearing the brace attempts to turn his toes out, he becomes actively uncomfortable; and in pulling away from the pressure of the brace, he assumes the overcorrected attitude which is intended to become habitual.

It is a fact unfortunately not universally recognized that the muscles of the weak foot have become stretched, relaxed and weakened in proportion to the length of the period of their accommodation to the faulty attitude of the foot. By a proper combination of rest and exercise, they may be enabled to "take up their slack"; but it is exactly this combination that the patient is not willing to give them. In short, it is the lack of respect with which the individual regards his feet that makes proper treatment so difficult. He will take time from business to devote to the treatment of an abscess at the root of a tooth from which he has never had any symptoms; he will give up days to the

correction of an error of accommodation; but the idea of staying off his feet out of consideration for an acute foot strain appeals to him as absurd, unless an element of the mysterious and bizarre be added. This is the basis on which lies the success of the tendon-lengthening and other operations for the relief of the weak foot. If the patient can be so impressed with the gravity of his complaint that he is willing to submit to an operation, the prolonged rest in plaster of Paris enables the relaxed ligaments and muscles to contract in the overcorrected position, and when he emerges from his confinement, the operative scar serves as a constant reminder of the surgeon's advice as to gait and posture. It is only in exceptional cases, however, that actual shortening of the Achilles tendon makes such a procedure necessary.

It is as a mean, therefore, between depending solely on the patient's attention to the directions given him, and placing his foot in plaster—the fool-proof preliminary method of

treatment—that we have recourse to the proper brace. This forces the patient when walking to employ his muscles with the foot held in the correct attitude, and when he is at rest serves as a splint to prevent his foot from sagging into the attitude of deformity, and again overstraining his weakened muscular and ligamentous supports.

It is not my purpose to maintain that brace treatment may be uniformly successful. While it is acknowledged that the fitting of a tailor-made suit is a procedure calling for a high degree of skill, it appears to be assumed that any one, from surgeon to chiropodist, should be able to fit a rigid metal support to a weight-bearing surface and make it fit comfortably the first time. This impression should be dissipated. The process implies a familiarity with the handling of plaster of Paris, the molding of casts, the vagaries of the brace maker and, above all, of the patient.

The cast of the entire foot should be taken with the foot on its side, in the corrected and nonweight-bearing

Fig. 2.—The body weight, when the feet are parallel, falling through the center of the foot.

attitude—in other words, the brace is to be fitted to the foot in its best possible form. Braces fitted to sole impressions of the foot are practically useless. The cast of the foot should then be trimmed according to what the surgeon thinks the particular patient will stand, always with the idea of obtaining the closest fit coincident with comfort. The outer aspect of the heel, where the lateral and plantar surfaces join, should be slightly built out with plaster to allow for the expansion of the heel when weight is borne; otherwise the outer flange of the brace will cause too much pressure at this point. The outline of the brace should be carefully marked by the surgeon himself. The heel and sole of the shoe should be raised a quarter of an inch on their inner borders. The patient should then be instructed that he is to accustom himself to the brace gradually. The first day that he wears it, he is to take it out of his shoe as soon as it hurts him. He is to do the same on the three or four following days. If at the end of that time he notices that the brace is still pressing into his foot sufficiently to cause a painful spot, he is to report to the surgeon, wearing the brace, so that adjustment of it may be made according to the marks on his foot. It should eventually be possible so to adjust the brace that it makes neither a mark on the foot nor a perceptible line on the shoe. Any external evidence on the shoe that the patient is wearing a brace is an indication of improper fitting.

Finally, one should always instruct the patient that his cure rests entirely with himself. Of course, there will always be found cases of such severity and of such long standing that cure cannot be hoped for. To the average patient, however, it should be made perfectly clear that his true recovery depends on himself, not on any form of support. He should be encouraged to look forward to the time when he may give up braces, lifted shoes and exercises, and depend for the future on his acquired habits of gait and posture. The first stage in the discarding process is that of the lifted shoe. He should change every other day, or, perhaps, at the beginning for only half a day, from the lifted to the flat shoe. When he has become accustomed to the flat shoe permanently, he should start a similar process with a brace; but during this period he should go so slowly and methodically that he can immediately lay his finger on any excess that causes a return of symptoms. In such an event he sets his program back to where he was a week before his symptoms occurred, and starts over again.

SUMMARY

The points which I wish to make in the rational treatment of the weak foot are these:

1. The average weak foot may be cured.
2. It may be cured in three ways:
 - (a) By proper shoes, plus a rigid supervision of the patient's daily exercise, gait and posture.
 - (b) By prolonged rest in plaster of Paris with the foot in the overcorrected attitude, plus or minus operative procedure, followed by exercises, etc.
 - (c) By the application of a proper brace, combined with daily exercises, etc.

I wish to establish a line of demarcation between the treatment of the weak foot and the treatment by palliative measures of the symptoms arising therefrom.

I do not expect that the average practitioner or specialist will depart from his present practice, or that

any large proportion of patients will make the esthetic sacrifice of abandoning the footwear that to them seems beautiful, or the lifelong habits of walking and standing that have descended to them from generations of dancing masters. I do believe, however, that the late wide experience of the war has awakened a large number of physicians, and a much larger number of laymen, to an interest in the foot and its disabilities. I believe that from now on there will be a steady improvement in the shape of footwear, particularly in men's shoes, and that the rising generation, in view of the possibility of universal military training, will be anxious to avoid the stigma of being physically unfit, and will therefore seek and require constantly better advice on the subject of foot management. I do not quarrel with long established measures for relieving symptoms which have in the past and will in the future satisfy large numbers of patients and practitioners.

I hope that eventually when a patient appeals to a surgeon for the relief of symptoms arising from a weak foot, the first point to be established will be whether that patient is to be treated for the relief of symptoms or for the cure of their underlying cause. I believe that no matter how enthusiastic a patient and physician may be at the outset, without military discipline it will always be difficult to effect a cure without applying a support. I hope that if a support is applied it will be a rational one, painstakingly fitted by a competent person, and applied with a perfectly clear mutual understanding of its purpose and of its temporary character.

MALIGNANT ENDOCARDITIS WITH PERFORATION OF BOTH MITRAL AND AORTIC VALVES

REPORT OF A CASE*

JOHN E. CONBOY, M.D.

NEW YORK

AND

HERMAN L. KRETSCHMER, M.D.

Genito-Urinary Surgeon, Alexian Brothers Hospital; Urologist, Presbyterian Hospital; Assistant Professor of Surgery, Rush Medical College
CHICAGO

Perforation of one of the valves of the heart occurring in malignant endocarditis is occasionally seen at necropsy and is not considered a very unusual complication. However, the finding at necropsy of perforation of two valves of the heart is of rare occurrence, and we believe it is of sufficient interest to warrant the subjoined report of a case.

REPORT OF CASE

History.—Private J. A. A., white, aged 27, admitted to one of the medical wards of U. S. Army Debarkation Hospital No. 5, March 3, 1919, directly from the overseas transport, had no untoward symptoms on board ship, and was admitted to the hospital in good condition considering the gravity of his cardiac condition.

The present trouble began, Feb. 1, 1919, following exposure, with indefinite pains in the right lumbar region which were aggravated by standing, and with inability to use the right leg. For a few weeks previously the patient had had a slight cough and occasional night sweats, and had lost some weight.

* From the medical wards, U. S. Army Debarkation Hospital No. 5, Grand Central Palace, New York City.

Physical Examination.—On admission, the head and neck were negative. The pupils were equal, and reacted to light and accommodation. The throat was negative, and there was no enlargement of the thyroid gland, but there was visible pulsation in the vessels of the neck. Examination of the lungs revealed the presence of a few moist râles over both bases, posteriorly.

The left border of the heart extended two finger breadths to the left of the midaxillary line. The apex beat was located in the fifth intercostal space to the left of the nipple. A systolic murmur was heard at the apex, and transmitted to the left axilla. A diastolic murmur was heard over the aortic region, and transmitted downward over the sternum. The heart was fully compensated.

The patient had a peculiar "waxy complexion," which persisted up to the time of his death. He gave one the impression that he was suffering from a very grave form of anemia.

Examination of the blood, March 12, revealed 3,270,000 red cells, 11,000 leukocytes, and 90 per cent. hemoglobin. The cellular structure was normal. Differential leukocyte count revealed 89 per cent. polymorphonuclears, 4 per cent. small mononuclears, and 11 per cent. large mononuclears. Blood cultures on the same day showed the presence of a pure culture of *Streptococcus viridans*.

Urinalysis, March 4, revealed clear, amber urine of acid reaction; the specific gravity was 1.018; there was a trace of albumin; no sugar was detected; there were a few granular casts. Urinalyses, March 6, 10 and 11, revealed no change.

Clinical Course.—From March 4 to 9, the patient's condition remained about as described. March 10, at 10 a. m., the patient very suddenly complained of severe dyspnea. The pulse rate was 140, the air hunger was very marked, and he was covered with a profuse perspiration. The extremities were cold, and the patient complained of chilliness. After the application of heat he appeared to be more comfortable and less dyspneic.

March 11, he had another very severe attack of dyspnea, and showed signs of collapse. The forenoon of the following day, he had another severe attack of dyspnea and was extremely restless. This dyspnea was followed by a sudden onset of cyanosis, and the patient died at noon, March 12.

Necropsy Findings.—Necropsy was performed one hour after death. The skin was very pale and somewhat emaciated. There were no scars or markings on the body.

The head was not opened. The abdomen and chest were opened by the usual incision. Very little subcutaneous fat was present, and the muscles were fairly well developed.

The pericardium was adherent to the parietal pleura. The tissue was seared, and a sterile pipet was thrust into the pericardial sac and about 10 c.c. of fluid withdrawn for culture. This culture showed the presence of a pure culture of *Streptococcus viridans*. The pericardial sac was then

opened and about 500 c.c. of clear, straw-colored fluid were withdrawn.

The heart was seared, a sterile pipet thrust into the left ventricle, and about 5 c.c. of blood were withdrawn for culture. This showed a pure culture of *Streptococcus viridans*. The heart was enlarged about two and a half times the normal size. The muscular structure was poor, and the muscles were somewhat flabby. The left ventricle was hypertrophied. In the heart, postmortem clots were found in abundance. The pulmonary and tricuspid valves were apparently normal, while the aortic valves were greatly thickened with dense vegetations, and their margins were very irregularly perforated. One of the cusps of the aortic valve showed a perforation which admitted the tip of the little finger (Fig. 1). There were small, warty vegetations on the wall of the aorta. The mitral valve showed the presence of vegetations similar to those seen on the aortic valve.

One of the cusps of the mitral valve was so sacculated that the sac would admit the thumb. There was a perforation at the bottom of the sac (Fig. 2), and warty vegetations on the chordae tendineae and papillary muscles, and above the walls on the wall of the left auricle.

There was one dense adhesion to the surface of the chest wall at the upper part of the lower lobe of the lung on the left in the midaxillary line. There was marked anthracosis. The bronchial glands were somewhat enlarged.

The liver was mottled and slightly enlarged, and there were numerous soft adhesions to the surrounding structures. The spleen was about two and one-half times the normal size. There were many adhesions and a small cyst with a thick capsule and filled with necrotic material. Both kidneys were adherent to the surrounding structures by firm adhesions. They were slightly enlarged and congested, with small petechial areas on the surface.

Microscopic Examination.—The lungs, heart, spleen, liver and kidneys were removed for microscopic examination.

Sections of the lungs showed that many of the alveoli were filled with desquamated epithelial cells, some of which contained a brown, finely granular pigment. A few of the bronchioles were also filled with epithelial cells. The blood vessels were not dilated, and there was no thickening of the alveolar or bronchial walls.

Near the pericardial surface of the myocardium was an area containing many small blood vessels and small round cells. The muscle fibers had been replaced by scar tissue, which was believed to be a small healing infarct. The myocardium otherwise seemed normal. The pericardium showed no change. Section of one of the aortic leaflets revealed the surface covered with great masses of fibrin, in the meshes of which polymorphonuclear leukocytes were entangled, and in and on the surfaces of which there were also enormous masses of bacteria. Some of the fibrin had undergone hyalinization. With the Goodpasture-Weigert stain the bacteria were found to be gram-positive cocci in long chains.

Fig. 1.—Perforation of mitral valve (A) and aortic valve (B) in malignant endocarditis.

In one of the sections of the spleen, many small areas of coagulative necrosis were seen. The pulp contained many leukocytes. The connective tissue was not increased. In another section there was a large infarcted area containing great colonies of bacteria. About this area there were many pigments containing phagocytes. There was much fibrous tissue about the margin of the infarct.

The cells about the portal areas of the liver were very much swollen and granular. About the hepatic vein the parenchyma cells were necrotic, and there were rather dense accumulations of leukocytes. In some of the areas the necrosis was not so marked, and in these the nuclei of the cells had disappeared; and there were many fat droplets within the cells. There was no increase in the amount of connective tissue, and the bile ducts seemed normal.

In one of the kidney sections, the epithelial cells of the tubules were very much swollen and granular, giving the lumen of the tubules a ragged or stellate outline. There was

Fig. 2.—Heart in malignant endocarditis: A, perforation of mitral valve.

no increase in the interstitial tissue. A small hyaline thrombus was found in one of the glomeruli. In another section, there was seen in addition to the changes mentioned above an area of coagulative necrosis. There was a moderate accumulation of leukocytes at the margin of the infarct.

2676 Morris Avenue—122 South Michigan Avenue.

Vomiting and Pyloric Stenosis.—Pyloric stenosis requiring surgical measures for its cure may exist many months or years without any vomiting at all, the patient's symptoms being merely those of more or less severe indigestion and discomfort. Experience teaches that the stomach begins to reject its contents only when the stenosis has been existing for a fairly long time; that in the earlier stages—when the condition is all the better for operation—the stomach does its level best to carry out its duty of driving the food along through the narrowing pylorus, only later giving up the effort and ejecting the food by periodic vomiting as the easier alternative.—Herbert French, M.D., F.R.C.P., *Medical Press and Circular*.

OPERATIVE TECHNIC IN SPINA BIFIDA *

JOSEPH RILUS EASTMAN, M.D.
INDIANAPOLIS

In few operative procedures is the mortality, both immediate and secondary, as high as that of spina bifida. The immediate death rate from shock, meningitis, etc., is approximately 33 $\frac{1}{3}$ per cent., while the secondary mortality from hydrocephalus, convulsions, etc., is equally great, resulting in an ultimate loss of from 60 to 70 per cent.¹ of the patients. According to Hildebrand² only about 39 per cent. make complete recoveries. Judicious selection of cases for operation, followed by rational, conservative technic would surely do much not only to reduce this discouraging mortality, but also to establish the surgery of spina bifida on a sound basis.

This very obvious point has been quite clearly set forth in the majority of writings on the subject. Thus, Beckman and Adson³ emphatically advise against operations associated with marked hydrocephalus or paralysis of the lower extremities unless, in the first instance, the hydrocephalus is either allowed to become stationary or is relieved, for example, by puncture of the corpus callosum; and in the second instance, unless it is understood by all concerned that operation will have no remedial effect on the paralysis. Thorburn⁴ and Tubby⁵ of England agree with these authors and enumerate frequent instances in which operations for spina bifida associated with hydrocephalus markedly aggravated the hydrocephalic condition.

Excluding, therefore, all cases associated with an increasing hydrocephalus as at least temporarily inoperable, we are reduced to: (1) operations on simple meningoceles in which the prognosis, if precautions hereinafter mentioned are observed, should be good, perhaps below 5 per cent., and (2) operations on meningocele and syringomyelocele, which are performed with little hope of remedying the paralysis and with the purpose only of removing a deforming tumor and preventing subsequent ulceration and rupture.

In the latter cases, despite the disappointing results in regard to paralysis, operations may be said to have a quasi justification, since few children thus afflicted ever reach maturity if not operated on; moreover, an unsightly tumor is removed. In the meningoceles, there is no contraindication to operation so far as the local condition is concerned, and no apparent reason why low mortality and good operative results cannot be secured in any of the three varieties of this group, as described in the excellent classification of Binnie⁶:

A. A defect of the posterior osseous wall of the spinal canal is present. The skin, spinal membranes and cord are intact. There is a hernia of the dura through the osseous defect. Fluid in greater or less quantity is present in the dilated subdural space.

B. The conditions are the same as in A, except that the arachnoid is involved in the hernia, and the collection of fluid is in the subarachnoid space.

6. Binnie, J. F.: *Operative Surgery*, Philadelphia, P. Blakiston's Son & Co., p. 716.

C. A defect exists in the dura as well as in the bone. Through these defects there protrudes a hernia sac consisting of the arachnoid. The skin, pia and cord are intact.

OPERATIVE TECHNIC

By transillumination, as used in hydrocele, one can determine with a fair degree of accuracy whether the sac contains nerves or cord, or both. At times, however, this may be misleading because of thickening and

posture of the operator has advantages which are obvious and important.

The first step of the operation consists in the taking of every precaution against the contamination of the wound. The importance of this cannot be overestimated, because the one imminent postoperative danger in spina bifida is meningitis from wound infection. Contamination is made especially dangerous because often the site of the wound not only lies near the anal

Fig. 1.—Suturing lower curved border of rubber dam protective to the skin of child's back: first step in making water-tight barrier against contamination of wound from excreta.

Fig. 2.—Circular incision begun in the collar of true skin which is present in most meningoceles. This circular incision to free the sac neck is conveniently and safely done by scissors-spreading dissection.

Fig. 3.—Circular skin and fat incision complete, and neck of sac free.

irregularities of the sac wall. In such cases application of a weak faradic current to various points on the sac may be of some diagnostic aid. Most frequently, however, the diagnosis of meningocele depends directly on clinical evidence, such as clubfoot, partial or complete paraplegia, or defective sphincter control, some of which are nearly always present in a greater or less degree if a nerve is involved in the sac.

It is usually advised to place the child in the ventral Trendelenburg position or in the hanging position of Babcock in order to prevent or reduce to a minimum the escape of cerebrospinal fluid following incision of

region, but because it also lies in the direct groove along which the infant's urine and feces are most likely to extend. Tubby,⁵ in discussing contraindications to operations in spina bifida, emphasizes that "lumbosacral tumors must be approached with caution because of the difficulty of avoiding fecal and urinary contamination." With this in mind, I place a piece of rubber dam over the tumor, and suture its lower border with fine chromic catgut to the skin of the child's back. The suture material, if quite fine, will allow of from eight to ten incursions and excursions of the needle to each inch of skin traversed. By reinforcing with collodion, this

Fig. 4.—Rubber-covered light intestine clamp applied to neck of sac to prevent escape of cerebrospinal fluid and entrance of infection.

Fig. 5.—Opening sac at thin and unusually transparent vertex of tumor.

Fig. 6.—If cord elements, as shown diagrammatically here, are present in sac, they can be freed while clamp offers protection against infection and escape of fluid, although the chance of benefit to paralysis resulting from operation in myelocele is practically nil.

the sac. This step, of course, is of considerable importance, but I prefer in its place the expedient of applying a light rubber-covered clamp to the neck of the sack, as is hereinafter described and advocated. With this step in view, the child is placed in the ventral recumbent position with the operator and his assistant seated on opposite sides of the operating table. In this, as in other delicate and minute surgical operations, the sitting

suture line may be made water tight. The rubber dam is then turned downward, and the second procedure is begun.

This step consists in dividing the circular collar of true skin which usually is present about the base of the tumor. The tumor may, of course, in the first variety of meningocele, have a covering of true skin; but in

those cases in which the tumor has no external covering except a very thin skin epithelium, there is nearly always a collar-like base of thick skin through which the true sac extrudes. By the employment of the scissors-spreading method of dissection, the circular incision through the skin at the base of the tumor may be made with little danger of the escape of fluid. The neck of the sac is then exposed as is the neck of the sac of the umbilical hernia in the Mayo operation, and is freed of all fat and connective tissue. The sac is then grasped between the rubber-covered jaws of a pair of light, delicate intestinal forceps.

The use of these clamps may be considered as of the highest importance in the surgery of spina bifida. It has been the practice, as mentioned above, to place the child either in the ventral Trendelenburg posture or in the hanging position of Babcock in an effort to minimize cerebrospinal fluid leakage. The clamps, however, preclude such leakage with much greater certainty than does position, and in addition they are a valuable agent in excluding infection from the spinal cord. It may be contended that clamps will traumatize whatever nerves may be present in the sac. In respect of this point it should be noted, first, that whatever

most likely to encounter cord and nerve structures in the median line. This is clearly a proper precaution unless one has been able to establish the diagnosis of meningocele beyond any doubt. If, however, the sac is opened at any point by a very small incision which is enlarged by scissors-spreading dissection, cord and nerves may be saved from trauma. If on opening the sac it is found to be free from nerve elements, a stout ligature is applied under the clamp jaws, the sac is cut away, and the clamp is removed.

The ligation of the sac, just mentioned, is performed as in inguinal hernia. Several writers, notably Bayer⁷ and more recently Beckman and Adson, have called attention to the analogy between spina bifida and inguinal hernia. I am of the same impression and believe, in addition, that the operative treatment, when possible, should be similar.

If the opened sac is found to contain cord or nerve tissue, these structures may in some instances be removed by blunt dissection, while the light clamp is still in place to prevent the escape of fluid and the entrance of infection. If necessary, the bony defect of the vertebral column may be enlarged to admit of such replacement. This removal of bone can be accom-

Fig. 7.—Tying stout transfixing ligature about base of sac, as in other forms of hernia.

Fig. 8.—Closing skin wound with running suture of chromic catgut reinforced with collodion.

Fig. 9.—Gauze square covering wound; edges strapped with adhesive plaster painted with collodion.

nerves are present in the sac will probably never functionate even if replaced, and secondly, that the brief application of such delicate clamps will no more cause permanent nerve injury than will gastro-enterostomy clamps injure the stomach, or obstetric forceps injure the fetal head.

The advantages presented by any method which assures against loss of cerebrospinal fluid should not be overlooked. Thorburn⁴ calls attention to this fact, saying, "It is in connection with this portion of the operation that its principal dangers—shock from profuse flow of cerebrospinal fluid or interference with nervous structures and meningitis—arise, and great caution should therefore be used to avoid a sudden escape of contents." Further he advises that "the upper end of the sac should be compressed with gauze to prevent a gush of fluid from the spinal cord." In addition to the advantages of the clamp method as just presented, the application of a rubber-covered light clamp greatly facilitates the replacing of the nerve elements in meningocele.

With the neck clamped, the sac is opened by snipping it through the thinnest part, which is usually at the vertex of the tumor. Binnie⁶ advises against opening the sac at this point since in meningocele one is

plished while the clamp is still applied. I have encountered cases in which the spinal canal was not large enough to receive the cord and nerve elements completely and others in which it was impossible to separate the thick ribbons of cord tissue from the sac. It is, of course, well understood, as mentioned previously, that operation in such cases promises little or nothing so far as relief of paralysis is concerned.

After the neck of the sac is tied and the clamp removed, no attempt is made to close the bony defect by an osteoplastic operation. The danger of this step probably offsets the few and doubtful advantages it may provide. I have known of no recurrences of this form of hernia which might be traced to the omission of this step; I have found no record of such an accident, and I believe it must be rare. The muscles are drawn together over the stump of the sac, and the skin wound closed with a continuous suture of fine chromic catgut, either transversely or longitudinally, depending on which is the more easily accomplished. Hemostasis should be complete.

Procedures directed against wound contamination, which were begun by stitching of the rubber dam to the child's back, are now completed. Collodion is

7. Bayer, C.: Ztschr. f. Heilk., Berlin, 18:405, 1897.

applied over the wound line. Over this a strip of gauze is placed, and its edges glued to the skin with adhesive plaster straps. This gauze and adhesive plaster are then painted with the collodion solution, after which the rubber dam protective is drawn up and laid flat on the back, and its three remaining margins are glued to the skin, as was the underlying gauze, by adhesive plaster straps. Next a small triangular piece of adhesive plaster is so applied that a sharp point passes downward between the buttocks, with the base of its triangle overlying the straps of adhesive plaster securing the lower border of the rubber dam. The adhesive plaster is then covered with collodion so that the zone of operation is sealed against infection by excreta.

In certain rare forms of spina bifida, as in spina bifida occulta, the suggestions offered in this paper are, of course, without value. However, in one rare form, the anterior meningocele, a successful operation for which is reported by S. Roux,⁸ the use of the clamp might remove many inconveniences. In the several forms of meningocele, it is submitted that the application of the light clamp will facilitate and render more safe the additional steps required in the attempt to deal in a radical way with this condition. With the simple meningoceles it is believed that the careful application of the technic herein embodied will make the operative mortality of this form quite as low as that in the analogous condition of inguinal hernia.

CONCLUSIONS

1. Spina bifida associated with increasing hydrocephalus is inoperable.
2. Operation should be performed in cases of spina bifida associated with paralysis only for the purpose of preventing subsequent ulceration and rupture.
3. A rubber dam sutured at one margin to the skin below the tumor, adhesive plaster, and plentiful collodion should be used to prevent fecal and urinary contamination.
4. A light, rubber-covered clamp applied to the neck of the tumor is the safest method of preventing the loss of cerebrospinal fluid and also of excluding infection from the cord.
5. The sac can usually be tied off as in inguinal hernia.

SURGICAL DRAINAGE FROM A BIOLOGIC POINT OF VIEW*

J. SHELTON HORSLEY, M.D.

RICHMOND, VA.

The biologic defenses of the body against disease, trauma and the wear of age are wonderful, but they are not perfect. If they were perfect, man would live forever. Particularly interesting is the manner in which the body protects itself against injurious foreign substances. The epithelial lined body cavities have more or less specialized methods of protection. The stomach, for instance, by vomiting emits food that is spoiled, and many drugs that are irritating or disagreeable to the taste, and sometimes even rejects substances that are thought to be nauseating or noxious even though they are not. The excessive salivation when nausea occurs probably tends to dilute the offensive material, or to protect the walls of the mucous membrane. Vomiting undoubtedly is a habit that was acquired in the early days of evolution. The more refined drugs or poisons that are a result of chemical manufacture have not created a similar defense by the stomach, and are often retained.

Foreign irritating substances in the rectum, the bladder or the larynx are also expelled by muscular action. Irritating matter in the nose causes a profuse secretion, which tends to wash away the offending substance. An irritating foreign body in the eye causes at once a flow of tears in an effort

Fig. 11.—Inverted position used by Babcock to prevent sudden escape of cerebrospinal fluid.

to wash it away, and at the same time the spasm of the muscles of the eyelids is probably due partly to an effort to expel the foreign body, as well as to protect against further injury.

In endothelial lined cavities or in solid tissue there is an attempt to wash away foreign irritating matter. This is done by the pouring out of serum from the lymph circulation in the neighborhood of the foreign substance, which is accomplished by the reversal of the circulation in the local lymphatics, so as to empty their contents around the irritating material. This is really the chief basis of surgical drainage.

In surgical drainage, mechanical measures that are followed by fortunate results would appear ridiculous if no biologic conditions existed. In preventing infection of a fresh raw surface, or in the so-called walling off of healthy tissue from the products of infection, gauze is often placed over the raw surface or as a coffer-dam in the abdominal cavity, and an abscess is drained through the center of this gauze packing. If we could convert this into a mechanical proposition and imagine that the pus was a solution of methylene blue and that it was flowing over this raw surface which had been covered with absorbent gauze to pre-

* 8. Roux, S.: *Rev. méd. de la Suisse Rom.* 38: 47 (Jan.) 1918.

Civil Versus Military Syphilis.—All returning Canadian soldiers whose military history sheets bear the record of venereal disease are given the Wassermann test before being discharged. In August, 1918, 2 per cent. of those returning reacted, all tertiary, noninfectious cases, for no primary or secondary cases are permitted to return. The average number of reactions in the civil population is estimated at from 8 to 12 per cent., showing four to six times as much syphilis in the civil population as in the army. It is not the civil population that has to fear the soldier, but the soldier the civil population.—Adami, *Canad. Med. Assn. Jour.*

* Read before the Southern Surgical Association, New Orleans, Dec. 18, 1919.

vent contamination, we know that both the gauze and the wound would be deeply stained. However, this method of protection does act in a beneficial manner, and a clean wound is often by this means kept from septic infection. The drainage of a peritoneal abscess is practically always up-hill and is usually successful. If mechanics were the only principle, how could an appendical abscess ever be drained by putting a tube down to it through the abdominal incision? The whole method of drainage really depends on the reversal of the circulation in the local lymphatics and is chiefly a biologic process. It is nature's effort to extrude a foreign substance.¹

A splinter in the finger which becomes mildly infected will discharge a thin seropus for days. This is nature's effort to expel the splinter. After it has been removed, the wound rapidly closes; and the lymph circulation, which was in part at least reversed in an effort to extrude the splinter, assumes its normal course, and probably in twenty-four hours after the splinter has been removed there is no further discharge.

The peritoneum and its underlying structures in the abdominal cavity constitute an enormous lymph space, and the lymph is here abundantly poured out in response to an irritation. The insertion of a drainage tube causes a reaction in which there is a flow of lymph in an effort to expel the drainage tube. Drainage of the abdominal cavity prevents positive pressure in the septic region, and also the drainage tube is a stimulus for a reversal of the lymphatic circulation. The packing of a fresh wound with gauze causes a similar reversal of the lymphatic circulation; and though pus may flow over this gauze from a deeper focus, the lymphatics, instead of absorbing the pus, pour out lymph into and around the gauze to extrude it. The beneficial action of the cigaret drain, which is soon clogged with coagulated lymph, is comprehensible when we look on it as a stimulus for reversal of the local lymphatic circulation.

In regions of the body in which the lymph supply is less abundant than it is in the abdomen, unless the infected focus is very small it will be necessary to utilize gravity when instituting drainage, because there is not a sufficient flow of lymph to flush the septic cavity thoroughly and constantly, as is the case with abdominal drainage.

Drainage in surgical operations may be classified under three heads:

CLASSIFICATION OF SURGICAL DRAINAGE

1. Drainage of solid tissue or endothelial lined cavities:
 - (a) Drainage of endothelial covered tissues of the abdominal cavity.
 - (b) Drainage of other endothelial lined cavities, as pleura, joints.
 - (c) Drainage of solid soft tissue, as muscle, fascia, fat.
 - (d) Drainage of bone.
2. Drainage of inflammatory products from infected epithelial lined hollow viscera, as the gallbladder and the urinary bladder.
3. Drainage of hollow viscera in order to restore function or to secure physiologic rest.

1. DRAINAGE OF SOLID TISSUE OR ENDOTHELIAL LINED CAVITIES

Considering first 1a, drainage of abdominal abscesses, we find, as has already been stated, that the abdomen has an enormous supply of lymph and that the successful drainage of an abscess in this region

consists, first, of relieving the pressure in the abscess cavity by opening it and inserting a drain; and, second, of inducing a sufficient reversal of the lymph circulation by the presence of the drainage material to cause much of the septic products to be washed away along the drainage track. If the drainage material reaches the abscess cavity so that the pus is not under positive pressure, and if the drainage is sufficient in amount and of the proper kind to act as a stimulus for reversal of the lymphatic circulation, so much lymph is poured out that practically a continuous irrigation is going on from the local lymphatics along the tube or track of the drainage material, and it is a matter of but little importance whether the drainage material is pointed up or down. But in other endothelial cavities (1b), such as the pleura or the joints, where the lymphatic supply is much smaller than in the abdomen or where the configuration is such as to make the drainage difficult, gravity must aid and the problem becomes more mechanical than biologic. Drainage here should be at the lowest point possible.

Drainage carried down to the sutured bowel frequently results in a fistula, particularly if gauze in the form of a cigaret drain is employed. The reversal of the lymphatic circulation in the neighborhood of a recently sutured intestinal wound, which will direct the current of lymph to the drainage, interferes with the normal process of repair in the intestinal wound, causes a weak fibrinous deposit, and diminishes the nutrition of the repairing bowel; consequently, the sutures readily break down and a fistula results.

In drainage of muscle, fascia and fat (1c), gravity drainage must be considered, but the biologic problem is also prominent. An abscess in the thigh heals better if gravity drainage is instituted. The drainage material should be sufficient not only to carry off the secretion but also to excite the local lymphatics to reverse their circulation. The local lymphatics, being much less abundant than in the abdomen, cannot usually furnish enough lymph to cause the flushing out of the septic products, as occurs in the abdomen. In rapidly spreading inflammation, wide incisions and drainage are useful in relieving the pressure that is made by the binding fascia or skin, and in reversing the circulation of the lymphatics and so preventing absorption of much of the septic products into the main lymphatic trunks.

The old operation of "fence rail" incisions along the margin of an advancing erysipelas causes the pouring out of lymph from these cuts and the diversion of the lymph current, which would otherwise carry the septic products to further uninfected regions. The undermining of the skin and insertion of tubes or gauze drainage from point to point make the pouring out of lymph along the drainage material even greater than after a simple incision.

That the reversal of the circulation is the chief biologic process by which surgical drainage acts beneficially in solid soft tissue can also be recognized when there is a small abscess in a large amount of inflammatory exudate and it is impossible to locate the small abscess cavity. If a drain is placed in the immediate neighborhood of the abscess, it frequently opens into the drain. It seems probable that this occurs because the lymphatic current attempts to extrude the drain and so the products of the abscess are carried in this direction, and the abscess burrows to the tube.

The drainage of tissues whose lymphatic trunks have been clogged and where, consequently, edema is present depends on an effort to increase the lymphatic circula-

1. Horsley, J. S.: *The Value of Biologic Principles in Surgical Practice*, J. A. M. A. 72: 1263-1266 (May 3) 1919.

tion or to create new lymphatic connections. In the operation of Handley in which long threads of silk are placed under the skin in edema of the arm, lymphatic channels form along the threads. In the operation of Kondoleon, the deep fascia of the arm or leg is split in order to promote an anastomosis between the deep and the superficial sets of lymphatics and so to divert the lymph current from the superficial to the deep lymphatic trunks.

Local edemas that are persistent are usually caused by blockage of the lymphatic channels and not by interference with the blood circulation. The edema that sometimes appears in the arm after a radical operation for cancer of the breast in which the axilla is thoroughly dissected is due to the removal of the lymphatics. If this immediately follows operation, it may disappear when the collateral lymphatic circulation is established; but when a late edema results it is frequently because the lymphatics have become plugged with cancer cells; and such an edema is ominous. Resection of the axillary vein if the lymphatics are in satisfactory condition is followed by but little if any swelling in the arm, and that of a temporary nature. A phlebitis causes edema only when the lymphatics around the vein are involved in the inflammation.

Drainage of wounds after radical operations for carcinoma in solid soft tissue should always be done. This is not so much in order to carry off the fluids that may accumulate in the wound, as an effort to reverse the circulation of the lymphatics which may be induced to pour out their contents in the direction of the drainage tube and so to discharge through this drainage cancer cells that have been left in the wound or that may have lodged in the open lymphatics. This is an important step in many radical operations for cancer, as after operations in the neck or on the mammary gland.

Drainage of bone (1 d) involves problems of a somewhat different nature, because of the structure of bone. Bone is compact, rigid tissue in which lime salts are arranged in an orderly way. On account of the rigid structure it is impossible for either the blood vessels or the lymphatics to form, or for the lymph current to reverse as readily as in soft tissue. Before drainage can be accomplished or any effective stand against infection can be made, the lime salts must be removed, so converting bone into what is practically soft tissue. For this reason, in areas of inflammation bone is always soft. Around an irritating substance in bone, whether accompanied by infection or not, lime salts are absorbed. When this is accomplished the offending material becomes loose and is prepared for extrusion. If, for instance, a piece of iron, as a screw used in plating bone, is inserted into a bone, the lime salts in the neighborhood of the screw and of the plate are absorbed. The screws, which may have been very tight and firm when inserted, gradually become loose. This induced osteoporosis around the screws and the metal plate is just the reverse of what is desired when a fracture is to be repaired, and it accounts for the frequency of nonunion after the plating of bones.

The numerous so-called abscesses at the roots of teeth are probably often the result of the reaction of the bone in the neighborhood to some material that was used in filling the cavities in the roots of the teeth. Undoubtedly apical abscesses frequently occur, but it is probably equally true that an osteoporosis sometimes interpreted as an apical abscess may be sterile and due

to the reaction of the bone to the material with which the root of the tooth has been filled.

Because of the poor lymphatic supply of bone and its rigid walls which protect its vessels, a bone abscess may be more readily disinfected by means of strong antiseptics, such as phenol (carbolic acid), than if the abscess were in soft tissue. Here, as disinfection can be more thorough, the necessity for full drainage in the milder chronic infections of the bone is not so great if the diseased bone has been removed as it would be in soft tissue. Consequently, "fillings" or "bone plugs" are utilized.

2. DRAINAGE OF INFLAMMATORY PRODUCTS FROM INFECTED EPITHELIAL LINED HOLLOW VISCERA, AS THE GALLBLADDER OR THE URINARY BLADDER

Drainage here involves principles different from the drainage of an abscess that has formed in solid tissue. This drainage not only is for removing the products of infection, but serves a double purpose of also giving physiologic rest to the infected organ. The drainage of a septic gallbladder that may be filled with pus carries off the products of the bacteria and at the same time gives rest to the gallbladder by preventing distention, and this removes both a stimulus for contraction and the tension that would occur on the distended walls. Drainage of this type does not have to be gravity drainage. If a sufficient opening is provided in the general axis of the peristaltic current, it is all that is necessary. In draining an infected urinary bladder, for instance, an opening made at the top of the bladder is as satisfactory in securing results as an opening at the bottom.

When these hollow muscular organs are contracted, a small opening will insure the viscera keeping empty if it is made in due regard to the action of peristalsis. Even in such instances, however, the beneficial action of the drainage is not solely removal of the contents of the hollow viscera or the giving of physiologic rest. It seems highly probable that reversal of the lymphatic current is also of importance here. This appears to be borne out by the results of drainage of the bile tracts in inflammation of the pancreas. It is well known that chronic pancreatitis can best be treated by prolonged drainage of the bile tracts; and drainage of the common bile duct for this affection seems to be particularly effective.

The work of Deaver and Pfeiffer² on pancreatic and peripancreatic lymphangitis is interesting in this connection. They call attention to the anatomy of the lymphatic supply of the pancreas and its ultimate connection with the lymphatics of the bile tracts and gallbladder. They say:

To the objection that infection to be carried into the pancreas must stem the efferent lymph current and force the valves, the answer can be made that every one has seen infection in cellular tissues proceeding in a reverse direction to the lymph current. Thrombolympangitis readily diverts the normal lymph course, and infection easily destroys valves. The force of pathology here, as in so many other instances, perverted the normal function.

If infection of the pancreas can be through the lymphatic supply from the gallbladder or the galltracts, as Deaver and Pfeiffer assert, it seems that the method of relieving this infection is to reverse the lymphatic current and cause it to be diverted toward the drainage tube and the incision in the gallbladder or in the com-

2. Deaver, J. B., and Pfeiffer, D. B.: Pancreatic and Peripancreatic Lymphangitis, *Ann. Surg.* 58: 151-163, 1913.

mon duct, just as the lymph flow is reversed in the drainage of an abdominal abscess. Septic products that would be carried in the lymphatics from the infected gallbladder to the pancreas are thus diverted to the drainage tube in an effort to extrude it. If this diversion can be maintained sufficiently long to permit nature to build up the resistance of the pancreas to the infection and repair the damage already done, the patient may be considered cured. But if the drainage tube is removed too soon, there is no further stimulus for a reversal of the lymph circulation, and the pancreatitis recurs.

Too early resumption of function after drainage of inflamed hollow viscera frequently results in a recurrence of the inflammation. This may be due to one of three causes, or more probably to a combination of these causes: 1. There may be an accumulation of secretion that is not free from the products of the inflammatory process. 2. There is an interruption of physiologic rest. 3. There is a change in the lymph current from that which had been instituted by the drainage.

3. DRAINAGE OF HOLLOW VISCERA FOR PHYSIOLOGIC REST

In enterostomy, the operation may be done to sidetrack the normal contents of the hollow viscera and so to afford less work for the diseased tissue below the point of opening, as in colostomy for disease of the large bowel farther down. Drainage may be instituted to prevent distention of a hollow viscus and so induce rest in order that an operative wound may heal. This principle is put into practice in such operations on the bladder as for vesicovaginal fistula when a self retaining catheter is placed in the urethra, and in the introduction of a tube through the rectum and through the site of resection of the sigmoid or left colon in order to draw off the gas and prevent distention in the region of the operation. This principle of drainage is often utilized after the removal of stones from an uninfected gallbladder.

DRAINAGE MATERIAL

The material for drainage must be considered not only with regard to transporting the products that are to be drained, but also with regard to the biologic influence of the drain on the local lymphatics. Certain substances call for a more pronounced flow of lymph than others. Rubber, for instance, is not so irritating to tissue as gauze. When gauze is placed over a raw surface, the local lymphatics pour into the gauze quantities of lymph. This is nature's effort to extrude an irritating foreign substance. When the lymph has coagulated, the meshes of the gauze become entangled with the wound; and an effort to remove the gauze before this fibrin has softened results in tearing the delicate tissues of the wound and injures its granulations, causing bleeding. An ideal drainage material would be one which, on the one hand, is a pronounced stimulus for the lymph to be poured out along the drain, and, on the other hand, would not be sufficiently attached to the raw surface of the wound to injure it. This material has not yet been found.

Rubber drainage tubes are frequently used, and have the advantage of draining off inflammatory products readily; but they do not provoke such an outpouring of lymph as gauze would. Naturally, however, the larger the tube the greater the irritation, and the more pronounced the stimulus for a reversal of the circulation of the local lymphatics. Consequently, for draining an

abdominal abscess, it is often found that a large tube does better than a smaller one, not because the smaller one is insufficient to carry off the serum or the pus, but because the small tube is not large enough to provoke a sufficient amount of reaction among the local lymphatics. Frequently the advantages of both gauze and rubber are combined by placing a gauze strip inside the tube or by wrapping strips of gauze in rubber tissue or rubber dam, which is called a "cigaret drain," and using this in addition to a tube. In this way the gauze which is exposed at the end of the cigaret drain causes a more pronounced flow of lymph than the rubber tube alone could produce, and the tube drains away the lymph that is thrown out to extrude the gauze and the tube. Drainage material should not remain too long in a wound, else it will act as the infected splinter mentioned above.

Combinations that are effective have been worked out to a large extent empirically. Sometimes strands of catgut, silkworm-gut, or strips of rubber tissue are inserted into a wound in which it is anticipated that there may be a collection of serum or broken down fat on account of the nature of the wound. This foreign substance, the drainage material, directs the current of the lymphatic flow toward itself and so prevents an accumulation in the tissues which might later become a culture medium for bacteria. An opened superficial abscess often needs no drainage material, for the necrotic products of the inflammatory process are a sufficient stimulus for drainage.

ENCAPSULATED FOREIGN BODIES IN THE PERITONEUM

If such foreign materials as gauze or cork are left in the abdominal cavity under sterile conditions, they are rapidly surrounded by a deposit of fibrin, as shown by Hertzler.³ This fibrin, which is coagulated lymph, soon is covered with endothelium and takes on the characteristics of peritoneum. If the gauze is left for a number of weeks or months, it may intrude into a neighboring hollow viscus and be expelled, as this may be the point of least resistance and, consequently, of greatest pressure. Instances are recorded in which gauze that has been accidentally left after a surgical operation has been expelled by the bowel or by the bladder months or years later. Sometimes, however, the gauze is completely encapsulated with a cystlike wall and becomes so thoroughly infiltrated with fibrin that partial organization takes place. Portions of the gauze may be disintegrated and removed by phagocytes, and the connective tissue penetrating the rest of the gauze is so intimate that it may have to be dissected away with much difficulty.

3. Hertzler, A. E.: *The Peritoneum*, St. Louis, C. V. Mosby Company, 1919, 1: 251-253.

Mental Hygiene.—As far as treatment and care of mental abnormals are concerned, it is necessary in each locality to determine the number of feeble-minded, epileptic, insane and psychopathic among the population, to inquire into their individual needs, and finally to provide facilities for scientific care and treatment. In connection with prevention the public must be informed concerning certain salient facts relating to mental disorders and taught through newspaper and magazine articles, leaflets, and public addresses, what is practical in the way of preventive measures. Prevention and treatment are intimately bound together, because when the feeble-minded, for example, are segregated in institutions and farm colonies, they are prevented from reproducing their kind.—C. M. Hincks, *Am. J. Pub. Health* 9:353, 1919.

LATE RESULTS IN THE RADIUM TREATMENT OF CANCER OF THE UTERUS

J. LOUIS RANSOHOFF, M.D.

CINCINNATI

What place shall radium have in the treatment of carcinoma of the cervix? This is a question of vital importance, as it concerns the treatment of a disease of universal distribution, a disease which in spite of the efforts of the world's greatest surgeons continues to take its large annual toll of suffering and death.

Carcinoma of the cervix has long been one of the most fruitful fields for radium treatment. Thousands of cases are annually declared inoperable and must needs be aided by some other means than surgery. Because of its unusual accessibility, radium can be brought into close contact with the neoplastic cervix where it can exert its direct influence.

Radium has long been granted its position as the agent of choice in the treatment of inoperable cervical carcinomas. The question which now concerns us is whether it shall supplant the radical operation in the treatment of so-called operable cancers of the cervix. I say so-called advisedly, as the question of operability depends entirely on the judgment of the individual operator, and in numerous instances cannot be definitely decided until after the abdomen has been opened.

With the publication of an account of the Wertheim operation in 1898, and its adoption by the leading gynecologic clinics of the world, it was thought that a step forward had been taken in the war against uterine cancer; but now, after two decades, the Wertheim operation is still on trial. One of the most distressing phases of carcinoma of the uterus is the low percentage of operability among those patients applying for relief. In a decade, Clark¹ operated on sixty patients and estimated that during the same period more than 300 were refused operation, an operability of only 15 per cent.

In Jacobson's² collection of 5,027 cases, only 1,720, or a little over 31 per cent., were considered operable. In reviewing the statistics of the Wertheim operation it would seem that the higher the percentage of operability in a given series of cases, the higher the percentage of operative deaths. Probably more discouraging than the small percentage of operability is the high immediate mortality. The operative mortality of Jacobson's collected cases was 18.25 per cent. These figures, bad as they are, nevertheless leave too optimistic an impression, as they represent the work of the most skilled gynecologists of the world. In the hands of the great body of operating surgeons, the mortality is undoubtedly far larger.

Peterson,³ in his own cases, had a total primary mortality of 25.4 per cent. In speaking of the operation he says:

Unquestionably added experience has strengthened my belief that the extended operation for cancer of the cervix is an exceedingly dangerous one, always attended by high primary mortality. No one will be more glad to discard the radical abdominal method than will I, if I can be shown that more patients can be ultimately cured by less dangerous methods.

Turning again to Jacobson's statistics, of 1,090 patients operated on that were followed, there were

386 cures, or 35.41 per cent. of the patients that were traced, or only 19.32 per cent. of the entire number of patients operated on; but what is most striking is that only 11.72 per cent. of all those patients applying for treatment were cured.

Clark has struck the keynote of modern opinion of the Wertheim operation. He says:

If an operation or other therapeutic process is to have a permanent place in our armamentarium it must be sufficiently easy to make it available not for a few skilled specialists, but for the great body of surgeons working in every quarter of this and other countries.

In these days of low mortality percentages attending nearly all major operations, no operation can possibly gain headway which combines with it a shockingly high mortality and a large majority of distressing and desperate sequelae. The effect on the lay mind must be taken into consideration, for while one may have over 50 per cent. of ultimate cures among those patients that survive the operation, the effect on the average intelligent citizen is abhorrent, if for this number of survivors there have been twenty-five deaths, and for the other twenty-five a wretched existence attended by repulsive postoperative sequelae, followed by a painful and lingering death. It is possible that when we make a final summary of our combined experiences we may have to accept the conclusion that a less radical operation, even though it saves fewer patients, may be preferable when attended by a low surgical mortality and few or no operative sequelae.

A CONTRAST OF METHODS

Disregarding for a time the end-results of radium treatment of cancer, it is interesting to compare the two methods of treatment from other standpoints. Contrasted with the high mortality of the extensive operation for uterine cancers, there is practically no mortality from the radium treatment. In place of a dangerous operation with its attendant suffering, long stay in the hospital, and distressing postoperative sequelae, there is the simple radium treatment with a few days' stay in the hospital, no danger and little pain.

Again, while less than one third of those patients who present themselves for treatment are fit subjects for the radical operation, radium treatment is available for all classes of cases, no matter how far advanced. The immediate result of treatment, and the palliation of symptoms, the relief from hemorrhage, pain and foul discharge have been too frequently described to warrant further comment.

The conclusions published by Dr. Joseph Ransohoff and myself⁴ in 1916 remain unchanged. That is, in all cases the immediate results have been without exception good. The concern now is, Can radium permanently cure cancer of the cervix? If so, does the percentage of cure equal that of operation? If that is true, the conclusion is obvious.

The pendulum is swinging toward radium as the method of choice in the treatment of operable cervical carcinomas. With the report of later results, its position is becoming more definitely established. As early as 1914, there were some operators convinced that radium should entirely supplant operation. Dobbert⁵ in that year, from an observation of twenty-four cases,

1. Clark, J. G.: The Radical Abdominal Operation for Cancer of the Uterus, *Surg., Gynec. & Obst.* 16: 255, 1913.

2. Jacobson, quoted by Janeway: *Surg., Gynec. & Obst.*, September, 1913.

3. Peterson, Reuben: *Surg., Gynec. & Obst.* 23: 280 (Sept.) 1916; *Tr. Am. Gyn. Soc.*, 1916.

4. Ransohoff, Joseph, and Ransohoff, J. L.: *Ann. Surg.*, September, 1916.

5. Dobbert, T.: *Ergebnisse der Behandlung des Gebärmutters-Krebses mit Radium*, *St. Petersburg med. Ztschr.* 39: 97, 1914.

eighteen inoperable and six operable, concluded that it was justifiable to use radium alone in the treatment of operable cases. Cheron⁶ reported an inoperable case in which radium was used. Two and one-half years after treatment, death occurred from intercurrent disease. Necropsy revealed no trace of cancer.

In 1915, Döderlein⁷ definitely advocated the use of radium in operable cases. Pozzi,⁸ in 1915, had given up the Wertheim operation in borderline cases and treated them with radium alone. In cases which are decidedly in their inception, a simple vaginal hysterectomy is done, followed by prophylactic radium treatment. Flautau,⁹ in 1915, definitely relinquished operation in favor of radium. The title of his article was, "May We Trust Radium Alone in the Treatment of Uterine Cancers?" In the same year, DeGrafs¹⁰ reported both operable and inoperable cases free from recurrence four years after treatment.

A very important contribution is one of Recasens, a Spanish surgeon. In the beginning he used radium only in those cases too far advanced for operation; but later he used radium to the exclusion of operation. He believes that in very early cases, a cure by radium is almost certain.

RESULTS IN THE AUTHOR'S SERIES OF CASES

As Dr. Joseph Ransohoff and I began the use of radium in the treatment of malignant disease in February, 1914, this report represents the results of nearly six years' experience.

On my return after two years in the army, I was interested in the fate of those patients whom I had seen in the three years prior to my entrance into the service. With the exception of the last case, which was two months later, this series includes those cases observed between February, 1914, and April, 1917, a period varying from two and one-half to nearly six years. As far as possible, all patients were traced; those that could not be located were regarded as having succumbed to the disease.

There are in all thirty-two cases. This includes all patients observed, varying from those whose cases were operable to those in a terminal stage of sepsis. There are also included cases in which for one reason or another the treatment was not complete. It is interesting to note that eight of these patients had what was considered an incomplete course of treatment, that is, three or less radium applications. The average number of applications for all cases, healed and fatal alike, was six. There were six recurrent and twenty-six primary cases treated. There were two cases of cancer of the fundus, and thirty of cancer of the cervix, so that this report deals principally with cervical carcinoma.

Of this entire series there were six patients, or 19 per cent., well and free from all evidence of disease at intervals varying from nearly three to five and one-half years after treatment. In the two cases of carcinoma of the body of the uterus, the results have been disappointing. Neither of these cases, however, was operable. Nevertheless, I am of the opinion that these patients when possible should be operated on rather than treated with radium, as the operative mortality is

low and the end-results good. One of these cases is worth reciting in detail:

Miss C. M., aged 34, referred by Dr. Palmer, had been having uterine hemorrhages for eight months. Three weeks before my examination, a curettage revealed an adenocarcinoma of the body of the uterus, which was confirmed by microscopic examination. The first radium treatment was given, July 3, 1914. In July, 1917, the patient was well. During the fall of 1918, she developed a pernicious vaginal hemorrhage, which was controlled by roentgen-ray treatments. Examination revealed what was thought at that time to be a large fibroid. A month before, these hemorrhages had again recurred. A piece was removed for section and proved to be an adenocarcinoma. One reason for the persistence of this tumor was probably the age of the patient, as it is well known that carcinoma is far more malignant in young persons than in those who are older.

Deducting the eight cases in which an incomplete series of treatments were given, we have 25 per cent. relief from symptoms during this period. There has been no definite operable case in which the treatment has not been successful.

REPORT OF CASES

CASE 1.—Mrs. I. F., aged 53, six months before had noticed sudden pains in the lower abdomen and for four months had suffered from bleeding from the uterus. The family history was negative. Examination, April 28, 1914, revealed an ulcerating epithelioma involving the entire anterior lip of the cervix. The uterus, however, was freely movable. A small piece removed for examination revealed epithelioma. The first radium treatment was given, April 28, 1914, and the last radium treatment, Sept. 11, 1914. Hemorrhage ceased after the first three treatments, and there had been no evidence of recurrence. The patient was in perfect health. In July, 1919, examination revealed a normal movable uterus, with no evidence of any ulceration, a freedom from recurrence after five and a half years.

CASE 2.—Mrs. K. H., aged 71, referred by Dr. Bachrach, for seven months had had severe vaginal hemorrhages. Examination disclosed carcinomatous degeneration of the entire cervix. There was a microscopic diagnosis of carcinoma. The uterus, however, was movable. The first radium treatment was given, May 1, 1915, and the last treatment, May 29, 1915. There were in all four treatments. The patient was reported well, April, 1919, a freedom of recurrence after four and one-half years."

CASE 3.—Mrs. S., aged 45, referred by Dr. Oliver, had been bleeding off and on for eight months. She was very much exsanguinated and was severely emaciated. Examination revealed a cancerous mass filling the vagina. A microscopic diagnosis of carcinoma was made. Under an anesthetic the mass was curetted away, the vagina was cauterized, and 100 mg. of radium were inserted for twenty-four hours. March 20, 1915, the first treatment was given, and the last treatment was given, May 7, 1915. April 25, 1919, examination revealed the patient perfectly well and able to do her work. Her weight was 124½ pounds. Sept. 10, 1919, a rectovaginal fistula developed. Examination under anesthesia disclosed a very small fistula in the posterior vaginal wall, communicating with the rectum. This fistula was situated just above a very dense fibrous stricture. Under an anesthetic, the stricture was stretched and a very careful examination revealed no evidence of cancer. Here the stricture was probably due to the concentration of a large number of treatments in a short time, necessitated by the desperate nature of the case. An examination made a week ago demonstrated the fistula nearly healed and absolutely no evidence of any tissue remotely resembling carcinoma, a freedom from recurrence for four and a half years.

CASE 4.—Mrs. S. S., aged 65, referred by Dr. S. Wolf, had been bleeding for eight months. Examination disclosed the

11. Since this article was written, this patient has died of some intercurrent disease, at the age of 76.

cervix entirely replaced by neoplastic tissue. There were a foul discharge and hemorrhage. A microscopic diagnosis of carcinoma was made. The first treatment was given in February, 1916, and the last treatment in April, 1916. Examination, November, 1919, revealed the patient in excellent health. The vaginal vault and the remains of the cervix were covered by smooth, pliable mucosa; there was no evidence of a recurrence, a freedom from recurrence of nearly four years.

CASE 5.—Mrs. J. W., aged 50, referred by Dr. Newfarth, with symptoms present for eight months, had had severe hemorrhage. The site of the cervix was occupied by a crater and cancerous vegetation. It was probably a borderline case. Under gas oxygen anesthesia, a curettage was performed. A microscopic diagnosis of carcinoma was made. The first treatment was given, December, 1916, and the last treatment, July, 1917. Examination, December, 1919, revealed a woman in excellent health, with no evidence of recurrence. There was a small scar in the vault of the vagina covered with normal mucosa, a freedom from recurrence for three years.

CASE 6.—Mrs. B., aged 54, referred by Dr. Aitkin, was operated on for cancer of the uterus two years before. She had had hemorrhage for the past two months. The vagina was narrow, and there was a recurrence in the vault. The first treatment was given in June, 1917, and the last treatment in December, 1917. The patient reported by letter, November, 1919, that she was well, a freedom from recurrence of two and a half years.

COMMENT

We have here 19 per cent. of those patients treated free from recurrence for from two and one-half to five and one-half years; one patient for five and one-half years; two patients for over four years; one patient for three years, and one for two and one-half years. The latter case may perhaps be a little too recent to be definitely called cured. This percentage of cure may seem small, but it compares favorably with that following operation. Deducting the eight cases in which the treatment was incomplete raises the percentage to 25.

The remaining twenty-six patients are either known to have died of the disease, or have at present a recurrence, or could not be traced.

Just a word here as to technic, that is, the question as to whether the radium treatment should be preceded by a curettage or the cautery. From our observation it would seem that the results were the same one way or the other; therefore we have definitely given up both curettage and cauterization as preliminary to radium treatment, and now we depend entirely on the radium.

If the cases were chosen for radium treatment with the same degree of care that they are chosen for operation, I feel confident that the percentage of cures would be very large. This is not, however, the function of the radium workers, who should give an opportunity for relief to every person who seeks treatment.

There is scarcely any case so far advanced that some improvement may not be obtained from radium treatment. In this work it should be the province of all observers not to work for statistics, but to give every patient a chance, if not for a cure, at least for an amelioration of symptoms.

Contrast the results of these thirty-two cases in which there was a 19 per cent. cure, with the Jacobson statistics, in which there was only an 11 per cent. cure. Also remember that there was no fatality from this entire series of treatment. Contrast this with the 18.25 per cent. mortality from the radical operation. Contrast again the economic saving of weeks in the hos-

pital, the postoperative suffering, and the unbearable sequelae. I do not hesitate to state that in my opinion radium treatment should entirely supplant operation, not only in the treatment of inoperable cases, but also in the treatment of operable cases of cancer of the cervix.

METASTATIC ABSCESES OF THE THYROID ASSOCIATED WITH HYPERTHYROIDISM

REPORT OF CASE FOLLOWING REPEATED ATTACKS OF SORE THROAT

DAVID GREENBERG, M.D.

NEW YORK

The case here reported is of interest because of its possible bearing on the etiology of exophthalmic goiter. In spite of the recent advances made in the study of this disease, its etiology is still unknown. This case directs our attention to the possibility of a bacterial cause. The similarity of symptoms in acute febrile diseases and thyrotoxicosis is well known. It is therefore possible that bacteria, now recognized as the cause, even though remote, of some chronic, so-called degenerative diseases, such as some forms of asthma, nephritis, arteriosclerosis and subacute and chronic arthritis (which until very recently were considered beyond the realm of bacteria) may play an equally important rôle here as well.

REPORT OF CASE

History.—Mrs. B., aged 46, a native of the United States, and a life long resident of New York City, with a negative family history, and with a previous history of scarlet fever at 16, from which she had made a good recovery, with good habits, drinking tea and coffee moderately, had had a goiter for the past twenty years. As far as she recollected, it had come on at about the age of 22. It was small at first and gradually grew until at the time of examination it was quite large (about the size of a small orange). This goiter had not increased in size for the past five years, according to the patient's statement. The menstrual history was negative.

Examination.—The patient first came under my observation about August, 1916, when she had a peritonsillar abscess on the left side. The temperature was 104, and the pulse 100. There were fairly large, irregular, vascular and inflamed tonsils and a peritonsillar abscess, with bulging of the supra-tonsillar tissues on the left side. Over the thyroid region there was a fairly large tumor, evidently cystic in nature and slightly larger toward the right side. No tenderness was felt over the tumor, and no thrill or bruit. Because of the presence of the goiter a thorough search was made for signs and symptoms of hyperthyroidism, but none were found.

Treatment and Results.—The peritonsillar abscess was incised, and the patient recovered without any complications and without any symptoms referable to the thyroid appearing.

After about six months she was taken ill with a sore throat, and soon developed what clinically looked like a double quinsy. She was quite ill at this time, the temperature ranging between 103 and 105 F., and with a good deal of glandular enlargement in the cervical and submaxillary groups. Both supra-tonsillar areas were incised, but no pus was obtained; nor was her general condition improved. The redness and edema of the throat, tonsils and soft palate persisted, and the temperature remained at about 105. The patient became very toxic, and I took her to Lebanon Hospital, where she was admitted to Dr. M. Lederman's service.

Dr. Lederman reincised the throat, but obtained no pns. Several throat cultures showed no diphtheria, but did show the presence of streptococci and pneumococci. In view of the

irregular, high temperature and the absence of pus, a diagnosis of streptococcus sore throat was made. During the patient's stay in the hospital, traces of albumin, and hyaline and granular casts were found in the urine. The temperature, however, was reduced by lysis. The kidneys cleared up to a great extent, and she went home in good condition.

About seven weeks after leaving the hospital, she began to complain of some pain over the right side of the neck in the area of the right lobe of the enlarged thyroid, which was quite tender. She also complained of general weakness, some dyspnea on exertion, palpitation, and occasional diarrhea.

Examination revealed a rather striking change in the patient's general appearance. She looked markedly emaciated, had a very decided fine tremor of the hands and tongue, and a rapid pulse, from 150 to 160, but regular. The heart was enlarged; there were ringing sounds, but there was no adventitious sound, and there were no eye signs. The thyroid was larger than it had been, and moderately tender. There was a distinct thrill and, at times, a bruit over the thyroid; the temperature was 100.

A diagnosis of hyperthyroidism was made. The tenderness was thought to be the result of a possible hemorrhage with sudden enlargement and pressure on adjacent nerves.

The patient was put to bed, the diet was regulated and sedatives were given, but no improvement resulted. After about four weeks of medical treatment, I advised an operation, but she refused. Roentgen-ray treatment was, therefore, tried for about three months at Mount Sinai Hospital in the outpatient department, but no improvement was noted. The patient finally decided to be operated on, and she was admitted to the Presbyterian Hospital for operation.

During this period, while under medical and roentgen-ray treatment, she had two attacks of sore throat similar to the ones described, but of a milder character. Both these attacks were treated conservatively, and the patient recovered without incision of the edematous soft palate.

While in the Presbyterian Hospital she was observed on the medical service for several days, and a diagnosis of hyperthyroidism was made by the internists. She was then transferred to the surgical service for operation.

At the operation, which was performed by Dr. McWilliams under gas and oxygen anesthesia, the exposed gland was found to be cystic, especially in the right lobe. This lobe, together with the isthmus and part of the left lobe, was removed.

On sectioning, the gland was found to consist of multiple abscesses filled with a greenish-yellow pus. The report from the laboratory stated that cultures had been made of the pus, and that Type IV pneumococci were recovered. The gland showed areas of acute and chronic inflammation, as well as an increase in glandular material.

The patient's subsequent course in the hospital was rather stormy. After the operation, she developed a parotitis on the left side with edema of the face. She eventually made a good recovery. The pulse rate decreased, and the muscular tremor disappeared gradually. Now, two and one-half years after operation, she is free of all symptoms or signs of hyperthyroidism.

COMMENT

This case of hyperthyroidism appears to have followed repeated attacks of acute peritonsillar and pharyngeal infection. We may, therefore, feel justified in emphasizing these points:

1. Thyrotoxic symptoms may appear in cases of simple goiter, the result of an acute infection.

2. Bacteria may be a factor in the causation of exophthalmic goiter: if not directly so, at least effecting such changes in the physiology of the gland as to make its appearance likely.

3. Suppuration of a thyroid gland should be suspected when there is even slight pain and tenderness over the gland with enlargement, especially when there is a history of a preceding infection.

WORKMEN'S COMPENSATION, WITH ESPECIAL REFERENCE TO LOSS OF VISION

FRANK ALLPORT, M.D.

CHICAGO

Surprise is often expressed concerning inharmonious medical expert testimony. Doubtless dishonest medical evidence is sometimes heard, but most medical opinions expressed in court are honest, and divergent views between witnesses are dependent on varying degrees of knowledge, and personal experience. The human body and its diseases, possessing but little uniformity, can be variably interpreted by a plurality of honest and intelligent observers, especially in borderland cases in which demarcation lines are vague and indistinct.

Long experience in examining plaintiffs for injury cases inevitably produces skepticism and demands for objective indications, as a high percentage of such cases is, more or less, based on fraudulent claims, fostered and nourished by unprincipled attorneys, unwise friends, and the general desire to extract money from wealthy corporations. Employees have themselves to blame, therefore, for having built a structure inimical to their own interests, while employers may be congratulated on a more benevolent attitude toward their employees—even if produced primarily by strikes, unionism, legislation, etc., induced by previous unjust demands on labor by capital. Employers now desire to produce and maintain friendly relations with their employees, and demonstrate such intentions by good wages and working conditions, hospital care, willingness to concede financial awards for honest personal injury claims, etc., whereas union labor, with its bosses and organizations, seems determined to produce conditions as hard as possible for those men endeavoring to conduct the business of our country.

Honest medical expert testimony is, therefore, influenced by various conditions, and as a consequence is frequently inconclusive; and any proper effort toward systematization should fall on receptive minds.

Owing to variable conditions, compensation tables for damages cannot be invariably equitable, and should not be so regarded; they are merely basal conclusions on which to work. An accepted compensation table for monocular visual losses is an unaccomplished necessity; yet it can merely become a steadying foundation for judicial consideration, and medical testimony will always be necessary for learned opinions and interpretations of present and future conditions, such as corneal scars, retinal and optic nerve diseases, and vitreous opacities. State laws and medical opinions differ as to whether vision (after injury) should be estimated with or without glasses, forgetful of the fact that almost all eyes improvable by glasses possess refractive errors antedating the injury. As a rule, therefore, a claimant should be required to accept the visual results obtainable by glasses with the exception of monocular traumatic cataract cases in which the required lens is so strong as to create annoyance, through discrepancy, diplopia, etc. Under such circumstances, the chief advantage of an operation is to demonstrate to the patient the visual capacity of the eye, and to restore actually a seeing eye to the injured that can be used in case of accident to the other eye. This is a valid asset, and should be considered when judgment is awarded, especially when all expenses are paid by the employer.

ESTIMATION OF OCULAR DAMAGES

It has been asserted that the payment of sick bills by employers has no significance, for such and such is the law and there is an end to it. But not all laws are just laws, and the justice of this law is questionable. Why should an employer be held liable for accidents over which he has no control? If he furnishes good tools, good wages, a good shop, well ventilated and lighted, and equipped with accident preventing devices, and an employee through ignorance, carelessness or obstinacy is injured, why should the employer be held liable? For these cogent reasons, legislatures and courts should not deal with employers too harshly; heavy responsibilities have been thrust on them and they should be given all reasonable benefits of doubts, instead of being buffeted and excoriated whenever opportunity presents itself. It therefore seems reasonable and just, first, that ocular damages should be estimated on conditions prevailing at the time of litigation, unless reasonably positive and reliable evidence is obtainable as to future conditions; second, that visual conditions should be estimated with glasses, except, third, after cataract operations, when the visual result might be measured on a 50-50 basis; this means, for instance, that if, after a cataract operation, good vision is obtained of, say, 20/20 or 20/30, by a glass, the vision may be reckoned as about one-half of normal and compensation paid accordingly.

Referring to unjust legislation, how unfair to both employer and employee is the law rendering the employer responsible for the loss of both eyes, when one eye was lost before the employee entered his service, and his remaining eye has been destroyed while working for the employer. The law is unjust to the employer because he was not responsible for the loss of the first eye, and it is unjust to the employee because it renders the securing of work difficult, as many employers dislike the presence of the maimed, and refuse the assumption of unnecessary legal and financial responsibilities, however much they might desire to assist the handicapped. Besides this, a one-eyed man is more likely to be injured than a two-eyed man, because he can see on only one side of him, and also for the reason that if his seeing eye is injured during work by a cinder, etc., he is quite helpless, as he cannot see through the other eye. Thus a law intended to benefit the laboring man is obstructive to his prosperity, as it often legislates him out of work. The law should be changed and the employer should be held responsible only for the loss of the eye injured during his own service. The employee cannot even legally give the employer a written document releasing him from responsibility concerning the first eye if the second eye is lost during his service. This is almost, if not quite, unconstitutional, as it debars the employee from exercising the right of personal privilege.

Among the very frequent causes of personal injury litigation are the varying losses of vision in one eye, necessarily followed by estimations concerning visual impairment. This produces discrepant expert testimony, leaving the court in mental uncertainty, usually resulting advantageously to the plaintiff—he being the poor unfortunate, and the employer representing what is called corporate wealth.

As Snellen's test types represent to ophthalmologists varying degrees of vision, it has been assumed that Snellen's fractions must also represent varying losses of vision, and that, for instance, 20/40 indicates 50 per cent. of visual loss, 20/30, 33⅓ per cent. of visual

loss, etc. Such conclusions are erroneous and misleading, for Snellen and his followers never intended these fractions to indicate visual insufficiencies—they were merely an international language interpreting ocular refraction, and I am confident that Snellen himself would be astonished and amused at the absurd use of his fractions in our courts, in the awarding of damages to ocularly injured plaintiffs.

It must be evident to all who intelligently and impartially consider this subject that 20/40 does not indicate 50 per cent. loss of vision, nor 20/30, 33⅓ per cent. loss of vision. Indeed, 20/30 is practically no loss of vision at all, and does not reduce a man's earning capacity one cent a year. Technically, it represents a small visual loss and should be so regarded; but practically, the loss is almost negligible. Why, then, should courts continue such erroneous calculations, entailing great and unjust financial losses on employers, accident insurance companies, etc.? The mistake was natural, especially as it received partial ophthalmologic sanction; and once begun, the custom prevailed, particularly as no saner or more accurate method endorsed by ophthalmologists was proposed. If ophthalmologists will propose and endorse a fair and simple table of compensation for visual losses, of reasonable accuracy, there can be little doubt that our courts will adopt such a table, thus removing at least one element of doubt and discord from our tribunals. It must be remembered, however, that such a table must be exceedingly simple, and devoid of all technicalities, as otherwise it will never be even considered by our courts.

While various compensation tables have been proposed by which to estimate monocular visual losses, no table has as yet been suggested on which all interested factions seem to unite, although they all arrive at about the same financial conclusions; and meanwhile the courts continue delivering unjust decisions, guided by palpably erroneous deductions. In the interest, therefore, of fairness, simplicity and brevity, I submit a table, recently adopted by the Chicago Ophthalmological Society, which it is hoped may be universally and uniformly adopted. In constructing a compensation table for monocular visual losses in working men, three points must be considered:

1. What constitutes industrial blindness in one eye?
2. What is the maximum legal compensation for such blindness?
3. What are fair and diminishing percentages of visual losses from the maximum to the minimum?

Concerning industrial blindness, many opinions are possible. Real blindness in its last analysis means a loss of light perception. I consider an individual industrially blind whose vision is insufficient for ordinary work. The injured may be unable to continue a habitual avocation; but if sufficient vision remains to perform ordinary work by ocular assistance, industrial blindness does not exist. What, then, constitutes "industrial blindness"? The answer must be more or less arbitrary. After consulting with many ophthalmologists, lawyers, industrial commissioners and insurance managers, the Chicago Ophthalmological Society arbitrarily concluded that vision worse than 20/200 constitutes industrial blindness. This opinion is, of course, open to discussion, but it is not remote from a fair conclusion to both employer and employee. Let this view, therefore, be tentatively assumed, and let it be said for the purpose of progress that vision worse

than 20/200 represents industrial blindness or 100 per cent. loss of vision, entitling the injured to the maximum compensation for monocular blindness allowed by the state law. This varies in different states, but in Illinois it entitles the injured to 100 weeks of compensation at \$12 a week, or \$1,200. The minimum to be paid for the total loss of one eye is \$6 a week. In case the maximum or \$12 a week is paid, the amount is increased \$1 a week for each child of the applicant under 16 years of age, up to and including three children. In case the minimum or \$6 a week is to be paid,

COMPENSATION TABLE FOR VISUAL LOSSES OF ONE EYE

20/20 indicates	100%	of visual efficiency and	no	loss of vision
20/30	94.5%	" " "	5.5%	" " "
20/40	89.0%	" " "	11.0%	" " "
20/50	83.5%	" " "	16.5%	" " "
20/60	78.0%	" " "	22.0%	" " "
20/70	72.5%	" " "	27.5%	" " "
20/80	67.0%	" " "	33.0%	" " "
20/90	61.5%	" " "	38.5%	" " "
20/100	56.0%	" " "	44.0%	" " "
20/110	50.0%	" " "	50.0%	" " "
20/120	41.0%	" " "	59.0%	" " "
20/130	36.5%	" " "	63.5%	" " "
20/140	32.0%	" " "	68.0%	" " "
20/150	28.5%	" " "	71.5%	" " "
20/160	23.0%	" " "	77.0%	" " "
20/170	18.5%	" " "	81.5%	" " "
20/180	14.0%	" " "	86.0%	" " "
20/190	12.0%	" " "	88.0%	" " "
20/200	10.0%	" " "	90.0%	" " "

the amount is increased 50 cents a week for each child of the applicant under 16 years of age, up to and including three children.

Two points in the construction of a compensation table may be said to be now finished, namely, the meaning of industrial blindness, and the maximum compensation payable for this misfortune. The latter, it must be remembered, is definitively settled by most states and we have nothing to say about it. Individuals desiring personally to assume financial responsibility for expensive accident insurance are at liberty to do so; but when insurance is assumed and paid for by the employer, \$1,200 is the maximum amount payable for the loss of one eye in Illinois. The last step to be taken in constructing a compensation schedule is fairly and equitably to grade down the percentages and compensations, to accord with the amount of vision that is lost. This has been attempted in the accompanying Chicago Ophthalmological Society table.

EXAMINATION OF APPLICANTS BEFORE EMPLOYMENT

Before the subject of compensation for monocular visual deficiencies is dismissed, it seems desirable to suggest to employers of labor a simple method for extensively reducing the frequency of claims for personal injury, not only for ocular damage, but for all other accidents as well. Reference is here made to the skilful physical examination of applicants before assignment to employment. Perfunctory examinations should be discountenanced, as errors in either direction may lead to unfortunate results. Eye and ear examinations, for instance, should be performed by competent specialists, that correct ocular and aural conditions may be ascertained. Two instances will demonstrate the necessity for such examinations before employment:

CASE 1.—A man received a slight head blow three weeks after obtaining employment. Shortly after he claimed blindness in one eye. Examination disclosed old chronic simple glaucoma with atrophied disk.

CASE 2.—A man was struck on the head by a piece of coal; no wound was produced. In five weeks he complained of

deafness and discharge from one ear. Examination disclosed an old chronic otorrhea, necrosis, foul discharge, and tympanic polypi.

In spite of convincing medical testimony, both men recovered damages. If these men had been properly examined before employment, both these diseases would have been detected, and litigation would probably not have been begun, but if begun would have been unsuccessful. The proper examination before employment of applicants for work is an economical necessity, but it is useful only if properly performed by skilful and conscientious physicians. In this way physical records are established that are bound in many instances to save, in the aggregate, enormous sums of money—much more, in fact, than the cost of proper medical examinations. Besides this, many employees have unknown physical infirmities which, when disclosed, can be cared for, and perhaps cured, to the great satisfaction of the employees themselves. Finally, when bodily imperfections are understood by both employer and employee, such knowledge can make employers more considerate of the afflicted, and inspire them to offer suitable occupation for individual needs. Some labor leaders demand the abandonment of physical examinations, thus clearly disclosing their sinister intentions, and ignoring the fact that such examinations should be welcomed by both honest employers and honest employees. Nor can the idea be ignored that, if employers are to be held liable for accidents, they certainly have a right to know the physical conditions of their employees before they assign them to work.

ENDOTHELIOMA OF THE PLEURA

REPORT OF CASE

P. J. McDONNELL, M.D.

Major, M. C., U. S. Army; Chief of Medical Service

SCRANTON, PA.

AND

E. S. MAXWELL, M.D.

Captain, M. C., U. S. Army; Pathologist, Base Hospital No. 79, A. E. F.

CHICAGO

This case is reported not only because of the rarity of the occurrence of the condition, but also because of the interesting conditions which prevailed throughout the course of the illness.

REPORT OF CASE

History.—A white man, aged 31, first reported at sick call, Oct. 29, 1918, and was sent to a field hospital, where a diagnosis of ileocolitis was made. From there he was immediately transferred to a base hospital. There he gave a history of having had diarrhea for two weeks previously. He was suffering from headache, and incontinence of feces, but he had no fever; mentally he was stupid and somnolent. November 9, on the discovery that the right side of the chest was partially flat, 500 c.c. of serosanguineous fluid were removed. Apparently no pus cells nor organisms were found in the fluid. As the mental condition grew worse, and definite auditory hallucinations were present, a diagnosis of a hebephrenic type of dementia praecox was made.

December 22, the patient was sent to the psychiatric department at Bazoilles, where examination disclosed that his memory was poor, that he had persecutory delusions, and that he was confused and disoriented. After physical examination the diagnosis of fluid in the right chest, with possible empyema, was made. The mental condition was then

ascribed to the toxemia and exhaustion and the patient was transferred to the medical service. There the chest was explored with a needle, but no fluid was obtained; something solid, however, was encountered. Over the flat area, tactile and vocal fremitus were lost, and breath sounds were distant. Above the flat area there were coarse moist râles, and the breathing was only faintly heard. The mediastinal dullness was noted as widened, and the heart impulse as outside the nipple line. A needle had been inserted at numerous times and by different surgeons but no fluid had been found, and on each occasion the impression of solidity was obtained. At the time of this examination there was some bulging of the right chest, and the patient began to complain of pain in the right upper abdominal quadrant. The leukocyte count was continually around 60,000, with 94 per cent. polymorphonuclears; the temperature would often rise to 102 F. The roentgenologist consistently reported fluid in the right chest.

February 1, the patient with others was taken over by our hospital. He was unable to sit up, although he would continually ask to be allowed out of bed. His body was emaciated, and the face had a hectic appearance. He showed marked mental deterioration, with the talk and manner of speech of a boy. He was emotional, crying easily and usually begging to be sent home. He was well acquainted with his present surroundings and with all in attendance. His movements were coordinate, and there was no spasticity. He usually lay on his back, but he could easily move about in bed. The chest examination disclosed that the cardiac dullness was not increased, and the apex beat was but slightly outside the normal position. The left chest was negative. The right chest was markedly larger than the left, and at one place, anterior and just above the costal margin, bulged somewhat into a solid rounded bump. Everywhere there was absolute flatness. Percussion below the fifth rib anteriorly was like striking a board. Over the lower and midlobes, breath sounds were but faintly heard and at a great distance. They were much louder at the apex and along the spine. However, everywhere they were of transmitted quality, distantly tubular. No râles were heard. Fremitus was abolished. With the history of 500 c.c. of serosanguineous fluid having been obtained early, of the numerous dry taps with the needle meeting strong resistance later, of the wooden percussion note, of the uneven breath transmission along the spine, of the right-sided shadow on the roentgenogram, and especially of the absence of cardiac displacement, the diagnosis of a new growth was made. Opposed to this diagnosis were the disconcerting features of a very high leukocytosis with the increase in polymorphonuclears, and a consistently moderate rise in temperature. It was thought that perhaps there might be a degenerated area in the tumor mass with abscess formation. However, there were no rigors nor high elevations of temperature. The expectoration was not profuse, nor at any time blood stained, nor of bad odor. Even the urine was albumin free.

The patient was observed from almost every angle as he progressively grew weaker. One had to bear in mind that perhaps there was present a condition which could be relieved by operation. The roentgenologist could not definitely diagnose the lesion with plates, and the horizontal screen was not in good working order. Tubercle bacilli were never found. The Wassermann reaction was negative. The blood picture showed no atypical cells. The sputum typed Group IV pneumococci. The pain in the right upper abdominal quadrant came oftener and grew more intense. There were no paralyses, nor stupor, nor loss of consciousness up until the patient's death, which occurred March 14, 1919, five months after the first symptoms were noticed. Because of the patient's age and the absence of recognized signs of metastases or lung infiltration, the tumor growth was thought to be probably of connective tissue origin. Death came without any new signs appearing except in the last few days, when there was an impairment of the good lung.

Necropsy Findings.—The anatomic diagnosis was malignant tumor of the right pleura and lungs with extension into the liver, chest wall and left pleura, and metastasis into the brain and peritoneum.

The right chest, just external to the nipple line at the seventh rib, showed a distinct bulging which was slightly nodular. On removal of the skin and muscles, several grayish white nodules were found adherent to the chest wall. The right pleural cavity was obliterated by a nodular, grayish white, friable tissue from 1 to 3 cm. in thickness, being thinnest at the apex and thickest near the mediastinum. It was firmly adherent to the lung and chest wall. The diaphragm was replaced by the same tissue, which extended deeply into the liver. The left pleural cavity contained 200 c.c. of clear fluid. A few adhesions were present. Posteriorly the parietal and visceral pleurae were covered by numerous firm white tubercles, varying in size from that of a pinhead to that of a large bean. A few appeared anteriorly.

The right lung was firm, and on section appeared dry with a marked increase in interstitial tissue. In the upper lobe the bronchi were surrounded by a white fibrous tissue. Occasionally a distinct nodule of this fibrous tissue was seen. All lobes were somewhat atelectatic. The left lung was soft and air-containing, but somewhat nodular. On section the nodules were found to be white with definite strands of fiber visible. The neck organs and cervical lymph glands were not remarkable.

The peritoneum was smooth and glistening, and the cavity contained no fluid. The upper and external surface of the liver was adherent to the peritoneum with a comparatively firm, friable adhesion in which were many grayish white nodules of varying sizes. A few isolated grayish nodules, the size of a pea, were scattered over the visceral and parietal layers. The liver was pushed downward about 4 cm. Its surface, especially the upper anterior and external aspects, was covered by the same nodules. On section, the advance of the tumor was seen to extend from 2 to 5 cm. into the liver substance. The advancing margin was composed of small, round tubercles which seemed to coalesce with age.

In the intestine, about 1 meter below the beginning of the ileum, there was a gray nodule which involved the entire thickness of the intestinal wall. It was surrounded by a zone of hyperemia. On the cecum, near the appendix, there were two nodules, 1 cm. in diameter, but they seemed to involve only the peritoneum.

The spleen was moderately enlarged and the capsule was wrinkled and thickened. On section, a smooth surface the color of grape juice was presented. The right suprarenal was somewhat enlarged, and near its center there was a nodule the size of a pea and similar to those just described. The left suprarenal was not remarkable. The kidneys were small and pale. The capsule stripped easily, and the cortex and medulla were well defined. The stomach, pancreas, bladder and genitalia showed nothing of note.

The meninges were clear. The brain on section showed a cavity, 3 by 3 by 6 cm., above the left lateral ventricle. The wall of this cavity was composed of a layer of brownish red tissue, 1 cm. in thickness, and distinctly nodular. The cavity was filled with an amber fluid containing numerous cholesterol crystals and a small amount of granular debris. Several smaller cysts similar to this were seen in the white matter throughout the brain sinuses.

Microscopic Diagnosis.—Thickened Pleura: The bulk of the tumor consisted of fibroblasts and connective tissue cells. These were arranged in many bands which communicated freely with one another. In certain areas these cells were nucleated and showed active growth. Usually, however, no nuclei were demonstrated. Between these strands of cells were many nests of cells. Near the center of the thickened pleura these nests were small, and the cells markedly distorted. Near the periphery the cells were more plentiful and the connective tissue much less conspicuous. There was a marked variation in the size and in the staining characteristics of these cells. Some were large and polygonal and stained densely; others were large with pale staining protoplasm, while still others were small and pyknotic. The cells were formed in groups, and in some places had a slight glandular arrangement. Karyokinesis was seen in many cells.

Liver Metastasis: The liver cells were cloudy, and many contained fat globules. The fat was especially noticed in

the cells surrounding the central vein. The line between the tumor cells and the liver cells was marked by a thin zone of scattered round cells with an occasional polymorphonuclear. Usually this line was cleancut and distinct. Occasionally tumor cells extended beyond it. The tumor cells were identical in appearance and arrangement to those in the tumor of the pleura. There was, however, very little connective tissue in the liver tumors.

Metastatic Nodules in Left Pleura: The cells were identical to those described above. Those in advance filled the alveoli of the lung, and in many cases were limited to a given alveolus. Deeper in the tumor, however, the alveolar wall was represented only by a thin line of connective tissue.

Right Suprarenal: The tumor was identical in every way to those just described. Its extending margins were clear and distinct.

Metastasis into Brain: Here the cells were arranged in a more orderly manner. Many definite papillae were present. The margin invading the brain substance was somewhat more irregular, and frequently the cells extended deeply into the brain. However, the general characteristics of the tumor cells were the same as those of the pleura.

The microscopic diagnosis was endothelioma of the right pleura with metastasis into the liver, left pleura, suprarenal, peritoneum and brain.

COMMENT

Most likely the first symptoms in this case were produced by the metastases in the brain, as no history of the chest condition was obtained until later. The diarrhea, noted at first as incontinence of feces, the stupor, and the psychosis were the outstanding signs and the ones that caused the patient to come under medical observation. The growth proper was not detected early because it produced no painful symptoms and invaded no tissue that gave any local reaction. The pleural effusion was the first sign noticed in the chest, and this was some time after the mental symptoms had appeared. The metastases were doubtless of a blood vessel type, and those in the brain were probably the first given off. Neither the motor nor the sensory areas were attacked, but apparently the parts associated with thought activity were greatly disturbed. The nodules in the intestine may have produced the diarrhea. The liver was invaded directly through the diaphragm. The latter lost its identity on the right side and was replaced by the advancing growth. The necropsy findings in no way explained the consistently and extremely high increase in white blood cells. The metastatic areas in the brain were sterile and showed no inflammatory reaction. The fever was no doubt due to toxic resorption. The growth began in the right pleura at the mediastinum and extended along the diaphragmatic and later the costal portions, compressing the lung upward in its course. Death was the result of asthenia.

The Geographic Distribution of Diseases.—L. R. Grote declares that not enough statistics and other data have been accumulated as yet for what he calls nosogeography. This is a science of the future, to be based on geographic, climatic influences, racial differences, social and economic conditions, the biology of the causative agents, and the effect of human efforts at prophylaxis. He reiterates that there is no part of the world absolutely free from any of the constitutional diseases, or where the infectious diseases cannot get a foothold when the causal agent is imported. In discussing these five elements of nosogeography in the *Geographische Zeitschrift* 25, No. 7, 1919, he cites a number of puzzling facts, such, as the high tuberculosis death rate and the low cancer death rate—only 4 per ten thousand—in the Münster region, while the reverse prevails in the East Sea provinces, the cancer rate being 14 while the tuberculosis rate is among the lowest.

THE PRODUCTION OF AN ACUTE RESPIRATORY DISEASE IN MON- KEYS BY INOCULATION WITH BACILLUS INFLUENZAE

A PRELIMINARY REPORT*

FRANCIS G. BLAKE, M.D.

AND

RUSSELL L. CECIL, M.D.

NEW YORK

Many attempts have been made to produce influenza in animals, or to transmit it experimentally from man to man by inoculation of the secretions, both filtered and unfiltered, from the respiratory tract in cases of influenza, by direct exposure of the subject to patients with influenza, and by inoculation with cultures of *Bacillus influenzae* isolated from patients with the disease. In large part, the results obtained have been entirely negative. In the few instances in which successful transmission of the disease has been reported, the methods employed and results obtained by different observers have been to a considerable extent inconsistent.

During the course of an investigation of experimental pneumonia in monkeys produced by the intratracheal injection of pneumococcus and *Streptococcus hemolyticus*, a further series of experiments with *B. influenzae* was undertaken in the hope of throwing some light on the relation which this organism bears to epidemic influenza and to the pneumonia which so frequently complicates it. The results obtained have been of such interest that it seems desirable to present a brief preliminary report at this time. The work will subsequently be reported in detail with full protocols.

Two species of monkeys were used: *Macacus syrichtus* from the Philippine Islands, and *Cebus capucinus* from Central America. All were fresh stock and had not previously been kept in captivity in this country. No preliminary procedures to lower resistance or to injure the respiratory tract before inoculation were resorted to. The strain of *B. influenzae*¹ employed was originally isolated from a case of influenzal pneumonia in a child. When received it had been in subculture on blood agar for a period of six weeks, and was found to possess no virulence for white mice. Since it was well known that the pathogenicity and virulence of *B. influenzae* are extraordinarily labile and very rapidly lost on subculture on artificial mediums, it was deemed necessary to raise the virulence of the strain to a considerable extent if successful results were to be obtained. This was accomplished, in brief, by successive animal passages, first through a series of eleven white mice, and then through a series of thirteen monkeys. These animals were inoculated intraperitoneally, the attempt being made always to give a sufficiently large dose to kill the animal within from twenty-four to forty-eight hours. Presumably because of individual variation in resistance, the desired result was not always obtained. In order, therefore, to avoid delay and possible loss of virulence because of this circumstance, fluid was withdrawn from the peritoneal cavity of the inoculated animals from eight to ten hours after injection, when the bacteria were still

* From the Bacteriological Laboratories, Army Medical School, Washington, D. C.

1. We are indebted to Dr. T. M. Rivers of the Johns Hopkins Medical School, Baltimore, for the strain of *B. influenzae* used.

actively growing in the peritoneum, and cultures were prepared to be used for inoculation of a fresh animal on the next day in case the previously inoculated animal failed to succumb. By this means the virulence of the strain of *B. influenzae* employed was sufficiently raised so that 0.01 c.c. of a sixteen-hour blood broth culture injected intraperitoneally killed a white mouse within forty-eight hours.

It was then considered probable that the organism had attained sufficient virulence to warrant testing the effect of inoculating monkeys in the respiratory tract. Accordingly, a series of twenty-two monkeys were so inoculated. The material used for inoculation may be divided into three groups: (1) first or second subculture on blood agar or in blood broth of *B. influenzae* recovered from the peritoneal exudate or heart's blood of monkeys dying of *B. influenzae* peritonitis and septicemia; (2) first or second subculture of *B. influenzae* recovered from the respiratory tract of monkeys killed during the acute stage of the pneumonia produced by intratracheal injection of the organism, and (3) the peritoneal exudate of monkeys dying of *B. influenzae* peritonitis, the exudate being controlled as to its purity by microscopic examination of stained films and by culture on blood agar plates.

Two modes of inoculation were employed, and for convenience the experiments may be divided into two groups according to the method used. In one group, in order to determine whether *B. influenzae* would initiate an infection of the upper respiratory tract, and if so, what the characteristics of the disease produced might be, the material to be inoculated was introduced into the nose and mouth either by application with a sterile cotton swab or by instillation with a pipet. In the second group, the material was introduced into the lower respiratory tract by direct intratracheal injection with a Luer syringe, the needle of which was inserted into the lumen of the trachea between the tracheal cartilages just below the larynx, the special purpose of this series of experiments being to determine if possible the pathologic characteristics of *B. influenzae* pneumonia.

In the majority of the experiments, the monkeys were held under preliminary observation for a period of from three to seven days before inoculation, during which time morning and evening temperatures (rectal) were taken, and daily total and differential leukocyte counts were made. The methods of study after inoculation consisted in the observation and recording of clinical symptoms, in the taking of morning and evening temperatures (rectal), daily total and differential counts of the leukocytes, and blood cultures at irregular intervals. Since the disease produced did not prove fatal, most of the animals were killed and necropsies performed at varying intervals during the acute stage of the disease or immediately after recovery.

THE EFFECT OF INOCULATING MONKEYS IN THE NOSE AND MOUTH WITH BACILLUS INFLUENZAE

Twelve monkeys received inoculations of *B. influenzae* in the nose or in the nose and mouth, with the successful production in every instance of an acute respiratory disease which appeared to be identical with influenza in man. The amount of culture or peritoneal exudate inoculated varied from what could be introduced by the single application of a cotton swab previously dipped in the culture up to 1 c.c. in each nostril and in the mouth.

Clinical Course and Symptoms.—The onset occurred from three to six hours after inoculation, the first symptom being a variable degree of prostration, often extreme, the animals in many cases lying prostrate on the floor of the cage, eyes closed and very stuporous. This was accompanied by an abrupt rise in temperature varying between 103 and 106 F. in some cases, with only moderate or no febrile reaction in others. Symptoms of upper respiratory tract infection soon followed, frequent sneezing, blinking of the eyes and rubbing of the nose being the prominent initial manifestations. The subsequent course of the disease showed some variation, but in general it was that of a self limited respiratory disease of from three to five days' duration. In most cases, by the end of from twenty-four to forty-eight hours, the infection had spread to the lower respiratory tract, as shown by the development of a racking cough. A variable amount, usually scanty, of mucoid or mucopurulent nasal secretion appeared in which *B. influenzae* might or might not be found. The temperature reaction varied greatly and showed no constant type of curve, being analogous in this respect to the variable types of febrile reaction seen in influenza in man. The leukocyte counts showed during the active stage of the disease either a definite degree of leukopenia or no significant variation from the normal, leukocytosis occurring in only three cases on the third or fourth day of the disease coincident with the development of a complicating purulent sinusitis.

Complications.—Five monkeys developed an acute purulent sinusitis of the antrum of Highmore from which *B. influenzae* in pure culture or mixed with some other organism was recovered at necropsy. Two animals developed pneumonia on the third and fourth days, respectively. The onset of pneumonia was insidious, and the presence of the disease was suspected only because of a rise in temperature and moderate acceleration of the respiratory rate. Both animals were killed during the early stage of the pneumonia, *B. influenzae* being recovered from the lungs in pure culture in both cases.

Pathology.—Nine animals were killed, and necropsies with bacteriologic examination were performed. Those killed during the active stage of the disease all showed rhinitis, with purulent sinusitis of the antrums in five cases. Cultures from the antrums showed *B. influenzae* in abundance in three cases, moderate numbers in a fourth, and none were recovered in the fifth. In two cases, *B. influenzae* was present in pure culture; in two, other bacteria also were found. Six cases showed a tracheitis or tracheobronchitis. *B. influenzae* was recovered from the trachea or bronchi in all of these: in two cases, in pure culture; in four, mixed with other bacteria (*Staphylococcus albus*, nonhemolytic streptococcus, or a gram-negative micrococcus). Two animals showed a fairly extensive bronchopneumonia involving the right upper and lower lobes, and the left upper lobe in one; the left lower, middle and upper and right upper lobes in the other. This pneumonia, in brief, was characterized by extensive hemorrhage, peribronchial areas of consolidation with an exudate of leukocytes, mononuclear cells and desquamated alveolar epithelium and thickening and infiltration of the alveolar walls, absence of pleurisy, and considerable patchy emphysema of the peripheral lobules. *B. influenzae* was recovered in pure culture from the lungs in both cases.

THE EFFECT OF INTRATRACHEAL INJECTION OF
BACILLUS INFLUENZAE IN MONKEYS

Ten monkeys received intratracheal injections of *B. influenzae*, in amounts varying from 1 to 5 c.c. of culture or peritoneal exudate, with the successful production of pneumonia in seven instances. Two monkeys showed only a tracheobronchitis; one showed no evidence of infection. The symptoms of prostration and cough, temperature and leukocyte reactions were the same as in the preceding group. In addition, the respiration was accelerated. In two cases, the infection spread to the upper respiratory tract with the development of coryza and frequent sneezing. In one case, a general infection with *B. influenzae* septicemia and pericarditis ensued. In no case did the disease prove fatal. It seems probable, however, that death would have occurred in the monkey that developed septicemia and pericarditis had it not been killed.

Pathology.—Of the seven monkeys developing pneumonia, three were killed during the active stage of the disease with the recovery of *B. influenzae* in pure culture in all; four were killed immediately after recovery, cultures made at necropsy being sterile. In the two cases in which only a tracheobronchitis developed, cultures from the trachea at necropsy yielded *B. influenzae* in pure culture in one, and no growth in the other.

Two types of pneumonia were encountered: a widespread, patchy pneumonia with extensive hemorrhage and edema, little cellular exudate or infiltration, and patchy emphysema; or a bronchopneumonia with extensive bronchitis and bronchiolitis, thickening and infiltration of the alveolar walls with swelling, proliferation and desquamation of the epithelial lining, and areas of peribronchial consolidation in which the alveoli were filled with mononuclear cells, polymorphonuclear leukocytes, red blood corpuscles and desquamated epithelial cells in varying proportions. Fibrin was very scanty or entirely wanting, and the pleural surface was rarely involved. One animal showed bronchiectasis. These two types of pneumonia appear to be essentially identical with the types of pneumonia in man that have been ascribed to infection with *B. influenzae*, when uncomplicated by secondary invaders.

SUMMARY

Twelve monkeys inoculated in the nose or in the mouth with a strain of *B. influenzae* originally isolated from a case of influenzal pneumonia in man and subsequently raised in virulence by animal passage developed an acute, self limited respiratory disease of from three to five days' duration, characterized by sudden onset with profound prostration; the development of rhinitis and tracheobronchitis, with sneezing, cough, and the outpouring of a scanty mucoid or mucopurulent exudate; a variable febrile reaction, and either a leukopenia or no significant change in the leukocyte count. This disease was complicated in five instances by the development of a purulent sinusitis, in two by the development of a fairly extensive hemorrhagic pneumonia with areas of peribronchial consolidation. *B. influenzae* was recovered at necropsy from lesions of the disease either in pure culture or in association with organisms that are normal inhabitants of the upper respiratory tract of monkeys. The disease produced appears to be identical with influenza in man in its course, symptomatology, complications and pathology.

Of ten monkeys injected intratracheally with the same strain of *B. influenzae*, seven developed pneu-

monia, two developed tracheobronchitis without pneumonia, and one resisted infection. The general symptoms of the disease produced were the same as in the preceding group, that is, sudden onset, prostration, a variable febrile reaction, and leukopenia or no significant change in the leukocyte count. The disease was accompanied by a severe cough and accelerated respirations; and in two cases, infection of the upper respiratory tract ensued. *B. influenzae* was recovered in pure culture from the lungs, bronchi or trachea in those animals killed during the active stage of the disease. The pneumonia produced presented the same pathologic picture as that which was found in the two animals developing influenzal pneumonia following inoculation of *B. influenzae* in the upper respiratory tract, and appears to be essentially identical with that ascribed to pure influenza bacillus infection of the lungs in man.

CONCLUSIONS

1. *Bacillus influenzae* can initiate in monkeys an acute infection of the upper respiratory tract which may be complicated by acute sinusitis, tracheobronchitis and bronchopneumonia.
2. This disease appears to be identical with influenza in man.
3. *B. influenzae* when injected intratracheally will produce in monkeys a tracheobronchitis and bronchopneumonia, the pathology of which appears to be essentially identical with that which has been ascribed to pure influenza bacillus infection of the lungs in man.
4. In view of these facts and the constant association of *B. influenzae* with early uncomplicated cases of influenza, it seems reasonable to infer that *B. influenzae* is the specific cause of influenza.

SIMPLIFIED TREATMENT OF THE
ORDINARY VARICOSE ULCER

L. M. STEARNS, M.D.

KEARNEY, NEB.

Ulcer of the leg is by far the most common type of ulcer with which the medical practitioner has to deal, and its treatment is generally most unsatisfactory. The reasons for this lie in the fact that the patient will not consent to take the necessary time for the rest essential to successful treatment, until the ulcer becomes painful; or the physician contents himself with the application of some ointment and allows the patient to gain the impression that there is little else to be done. Many of these patients suffer for years from this extremely annoying condition, thinking that there is no help for it.

When these cases first come under observation, the surface of the ulcer is denuded, with a ragged, overhanging edge, while the base is filled with gray granulation tissue accompanied by a continuous discharge. There is usually more or less edema and a brawny condition of the surrounding skin, and if the ulcer lies over bone, there may be a secondary periostitis which stimulates the patient to seek relief. Bacterial absorption from the ulcer plays an important rôle in the causation of the local edema; usually this clears up following the healing of the ulcer, in spite for the fact that there may be more or less varicosity.

During the past few years, I have evolved a technic which seems to me very simple and applicable in most cases with the minimum loss of time to the patient.

The mode of procedure is as follows: The ulcer is first cauterized with fused silver nitrate, and the leg elevated for twenty-four hours, to clear the edema. Then a dressing, after the formula of Unna, is applied: gelatin, two parts; zinc oxid, one part; glycerin, three parts, and water, from four to six parts (depending on the consistency desired). These are mixed in a water bath and the paste is applied warm with a spatula to the entire leg from the ball of the foot to the knee, leaving the heel free. A roller bandage is immediately applied over this so that the paste penetrates the first layers of the bandage; if applied smoothly and evenly this makes an ideal supporting bandage and prevents a return of the edema when the patient is again ambulant. Forty-eight hours after cauterization, a small window is cut in the dressing over the ulcer. The slough is cleaned away with a sharp curet until the surface is clear, clean and easily bleeding; the edges will be found somewhat undermined.

With curved scissors the edges of the ulcer are trimmed away, removing a barrier to epithelization from the periphery of the wound. The tissue thus removed is placed on a piece of gauze moistened with physiologic sodium chlorid solution, and with a piece of dry, sterile gauze gentle pressure is made on the ulcer until all oozing has stopped. The edge is then coiled in the crater of the ulcer, and over this is placed a perforated piece of rubber to assist in drainage, and the whole is covered by a sterile dressing and a snug roller. Elevation of the limb should be continued for three days, when the wound should be dressed, after removing the rubber drain, with gauze impregnated with a 5 per cent. scarlet red ointment. The patient is now allowed to be up and about, but is cautioned to remain quiet for a few days longer or until epithelization of the wound is complete. The paste dressing is left on the leg for two weeks and is then reapplied if continued support is desired.

In sensitive patients, the area may be blocked with a 2 per cent. solution of procain.

GALLBLADDER DISEASE

SUMMARY OF FOUR HUNDRED AND TWENTY-FIVE CASES
TREATED AT THE HARTFORD HOSPITAL FROM
1914 TO 1918

A. W. BRANON, M.D.
HARTFORD, CONN.

This report is based on 425 admissions to the Hartford Hospital from 1914 to 1918 in which a gallbladder or gallduct disease was suspected or found during treatment. The hospital records have been studied in some detail, and a personal letter was sent to 350 patients who left the hospital, of whom 148 filled in and returned the questionnaire. I have tried to group some of the more important notations for analysis. These patients, both ward and private, for the greater part were admitted to, or transferred to, the surgical service for treatment. Each staff surgeon's work is represented, also a liberal sprinkling of private work done by nonmembers of the hospital staff.

I have arranged this report somewhat after the model of an individual history as taken by the house officer. As regards family history, there seems to be little of importance. Occasionally there was an interesting coincidence; for example, one patient, a physician's

wife, wrote me that she, her husband and their son were each recently operated on for cholelithiasis.

For convenience the ages are divided into decades, from 10 to 20 to 71 to 80 (Table 1). Complications and associated pathologic conditions have not been noted here.

TABLE 1.—AGE GROUPS

Age	Cholelithiasis No.	Cholecystitis No.
From 10 to 20	1*	6
From 21 to 30	41	17
From 31 to 40	83	18
From 41 to 50	92	20
From 51 to 60	89	17
From 61 to 70	32	6
From 71 to 80	9	3
Total	338	87

* A girl of 18.

There were eighty-three males and 342 females who came under observation, a ratio of about 1:4.

TABLE 2.—NATIONALITY*

	No.	Per Cent.
Americans	229	53.8
Russians	49	11.5
Swedish	18	4.2
German and Austria	21	4.9
Polish	20	4.7
Italian	26	6.1
Armenian	6	1.4
Greek	1	

* Fifty-five histories did not state the nationality, but no marked disproportion is evident.

TABLE 3.—OCCUPATION*

	No.
Housework	273
Labor	24
Shop	28
Sedentary	36
Nurses	5

* Fifty-nine histories did not state the occupation.

Under previous illnesses (Table 4) are noted the more important ones, not including the contagious diseases of childhood, one or more of which was recorded in nearly every case.

TABLE 4.—PREVIOUS ILLNESSES

	No.	Per Cent.
Marked constipation*	166	39
Recurrent attacks of tonsillitis	46	10.8
Typhoid fever	43	10.1
Scarlet fever	38	8.9
Pneumonia	31	7.8
Appendicitis	29	6.8
Rheumatism	25	5.8

* This not being mentioned in the other histories.

Of the 342 women, 151, or 44.1 per cent., had had children, and twenty-three, or 6.7 per cent., were unmarried.

Pain of some sort was almost a constant symptom, it being described in 84 per cent. of cases. Practically all patients had repeated attacks; many of them could ascribe an attack to some particular cause. Probably the most common cause in those having had children was labor. Not a few patients suffered an attack shortly after delivery.

Indiscretion in diet would precipitate an attack in many. A few patients could almost certainly expect

an attack following an alcoholic debauch, while constipation figured frequently.

The time of onset was not mentioned in most of the histories, but from those in which it was stated, about 50 per cent. were nocturnal.

The duration of gallbladder disease as determined by pain seemed to be of considerable interest when considered with the complications, the difficulty experienced at operations, and the advanced age of many of these patients when they eventually came to operation.

A few of the younger patients, and particularly those who had a cholecystitis, were admitted during the initial attack. The duration in the 283 cases in which this was stated is given in Table 5.

TABLE 5.—DURATION

Duration Years*	No.	Per Cent.
From ½ to 1	118	41.7
From 1 to 2	38	13.4
From 2 to 3	29	10.2
From 3 to 4	14	4.9
From 4 to 5	14	4.9
From 5 to 30	70	24.7

* In a few the duration was even longer than thirty years.

TABLE 6.—LOCATION OF MAXIMUM PAIN

Location	No.	Per Cent.
Right upper quadrant	179	50.5
Epigastrium	130	36.7
Right lower quadrant	27	7.6
General to abdomen	18	5
Radiation to back or shoulders	159	44.9
Colicky	148	41.8

The maximum pain as located in 354 cases is given in Table 6. The character was not definitely described in about half the cases. Other symptoms frequently mentioned were indigestion and vomiting, which were noted in 215, or 50.5 per cent. of cases. In 120, or 28.2 per cent., jaundice appeared, and loss of weight in fifty-three, or 12.4 per cent. The maximum point of tenderness as noted in 270 cases was located 177 times in the right upper quadrant; forty-eight times in the right lower quadrant, and forty-five times in the epigastrium. It was not localized in 155 examinations. On palpation, the gallbladder could be felt in forty-nine cases, the liver in six, and the pancreas in one.

A roentgen-ray examination of the stomach or gallbladder was made in seventy of the cases, with the reports given in Table 7.

TABLE 7.—ROENTGENOGRAPHIC REPORTS

Condition	Diagnosis	No. of Cases
Cholelithiasis	Adhesions about the pylorus	10
Cholelithiasis	Gastroparesis	8
Cholecystitis	No evidences of cholelithiasis	7
Cholelithiasis	Gastric or duodenal ulcer	8
Cholelithiasis	New growth	6
Cholelithiasis	Stomach and gallbladder appeared normal	17
Carcinoma of gallbladder with cholelithiasis	Gastric carcinoma	1
Cholelithiasis	Poor plates	5

Gallstones were demonstrated in two cases. In six cases gastric or duodenal ulcer was demonstrated in which cholelithiasis was also present.

Of the 425 patients under discussion, thirty-five, or 8.2 per cent., had previously been operated on for

cholelithiasis, a drainage of the gallbladder having been done; fifteen of these had recurrent cholelithiasis; three had stones in the common duct; fourteen suffered from cholecystitis and adhesions, and three from biliary sinuses. In two other cases the gallbladder had previously been removed; these patients returned with symptoms of stones in the common duct.

In all, 331 cases came to operation. Ninety-four patients either refused operation or were advised not to be operated on for some sufficient reason. Cholecystostomy was performed in 171, or 51.6 per cent., of cases; cholecystectomy, in 139, or 42 per cent. Adhesions about the gallbladder were broken up in twelve cases. There was primary closure of the gallbladder after removal of stones in four cases. No pathologic condition about the gallbladder was found in three cases, and in two cases the small bowel was opened for the removal of gallstones causing intestinal obstruction.

ASSOCIATED PATHOLOGIC CONDITIONS

The appendix was found to be definitely diseased and was removed in thirty-nine cases; cancer of the gallbladder in four; ruptured gallbladder and general peritonitis in four; gastric ulcer in three; duodenal ulcer in four; a perforation of the gallbladder into the duodenum in two, and a perforation of the gallbladder into the stomach in one. There was one case of acute pancreatitis with fat necrosis and there were twelve cases of chronic pancreatitis.

One patient had a painless jaundice of six months' duration, with congestion of the liver and marked loss of weight. A large stone was removed from the common duct, following which she made a complete recovery and is now well, four and a half years following operation.

TABLE 8.—AGE OF PATIENTS WHO DIED

Age, Years	No. of Patients
Between 61 and 70	7
Between 51 and 60	10
Between 41 and 50	13
Between 31 and 40	3
Between 20 and 30	2

MORBIDITY, CONVALESCENCE AND MORTALITY

The average length of time spent in the hospital following cholecystostomy was twenty-three and a half days, as against twenty-two and a half days for cholecystectomy. Of 148 replies to the circular letter, sixty were from cholecystectomy patients, of whom three, or 5 per cent., had recurrent pain since operation. Seventy-four were from cholecystostomy patients, of whom nine, or 12.1 per cent., had recurrent attacks of pain. Four were from patients who had adhesions about the gallbladder broken up; two, or 50 per cent., of these had recurrent attacks of pain. In one of the four primary closures the patient had recurrent attacks of pain.

Nine patients who were discharged without operation replied. Convalescence was recorded as satisfactory in 271 cases and as stormy in twenty-nine, while thirty-one patients died. Of these there were eleven cholecystectomies, one carcinoma of the gallbladder, in which nothing more than exploration was done, and nineteen cholecystostomies. It is a fact, however, that the more desperate cases, including one carcinoma with stones and four ruptured gallbladders with general peritonitis, were among the cases with drainage.

The operative mortality, excluding the four cases of general peritonitis and the one case of carcinoma in which the patient lingered on and died before leaving the hospital, is 7.8 per cent. Deaver, in 1916, reported 1,031 cases with a mortality of 7.2 per cent. Twenty-five New York hospitals reported a series of cases with a mortality of 8.3 per cent. Mayo reports 4,000 cases with a mortality of 2.75 per cent.

TABLE 9.—DURATION OF GALLBLADDER DISEASE IN PATIENTS WHO DIED

TABLE 10.—CAUSES OF DEATH

Myocarditis and general arterial changes	9
Pneumonia	6
Postoperative hemorrhage	5
Peritonitis	4
Pulmonary embolism	2
Fecal fistula	2
Typhoid fever	1
Acute nephritis	1
Abscess of liver	1

SUMMARY

It will be noted that when patients with gallbladder disease pass the 50-year mark, the operative mortality rises very abruptly, as out of the seventy-one patients admitted between 50 and 60 years, thirteen, or 18½ per cent., died. Of thirty-eight between 60 and 70, ten, or 26½ per cent., died; of twelve between 70 and 80, seven, or 68½ per cent., died, while out of 278 under 50, five, or 1.8 per cent., died.

When we consider the fact that the vast majority of cases develop before the age of 50 years, it would seem that we should try to prognosticate the eventualities and at least advise early operative procedures.

Of previous diseases, constipation is the most striking and of undoubted significance.

The addition to the twenty-nine previous appendectomies of the thirty-nine chronically inflamed appendixes removed at the time of gallbladder operation makes a total of sixty-eight, a rather large coincidence.

Of the acute infectious diseases in this series of cases, typhoid fever was not noted as frequently as recurrent attacks of tonsillitis, and only slightly more frequently than was scarlet fever, pneumonia or rheumatism.

When we add to the eighty-three males the twenty-three unmarried females and the 168 married women who did not give a history of childbearing, we get a total of 274 cases occurring independently of childbirth; and when it is recalled that the age of gallbladder disease in all patients coincides pretty closely with that of gestation, it does not seem that the latter is of unusual significance. (Undoubtedly there were some cases of pregnancy not noted.)

Indigestion without typical gallbladder pain was one of the most difficult symptoms to solve, and delayed the accurate diagnosis for a long time in many cases.

The comparative results of cholecystostomy and cholecystectomy in this series of cases show forty-four unsuccessful drainages against five unsuccessful removals.

A FORUM FOR THE DISCUSSION OF THE USE OF DRUGS
AND OTHER REMEDIES IN THE TREATMENT OF DISEASE.

USE AND ABUSE OF CATHARTICS*

(Continued from page 104)

THE CATHARTIC SALTS

EFFECT ON URINE

That portion of the saline which is absorbed is chiefly eliminated by the urine, producing a diuretic action in inverse proportion to the cathartic effect. Generally, of course, owing to abstraction of water by way of the intestine, there is a diminution in the urinary secretion for about twelve hours. This is followed by increased secretion of urine for perhaps the next twenty-four hours. Very dilute, as well as very concentrated solution, and also very small doses, or antagonizing the cathartic action by remaining in bed after taking the dose or by the use of morphin, all bring out the diuretic action at the expense of the cathartic effect.

The curious observation has been made that magnesium sulphate increases acidity and ammonium in the urine, while sodium sulphate decreases urinary acidity. The reason for this lies in the different degree of absorbability of the various ions yielded by these salts in the intestine. The magnesium ion is more slowly absorbed than the sulphate ion. Hence, more magnesium remains in the bowel, while the acid ion, in passing through the system, abstracts alkali and acidifies the urine. With sodium sulphate, the reverse is the case. The sodium ion is more rapidly absorbed than the sulphate ion. Hence, an alkaline wave passes through the system and into the urine. This might cause sodium sulphate to be preferred to magnesium sulphate in conditions of acidosis or when it is desirable to keep urinary acidity low.

CHOICE AND ADMINISTRATION

The cathartic salines differ among themselves in potency and palatability, as well as in details of action, all of which determine their choice.

The mildest and most inoffensive of the group is *magnesium oxid*, which, in the form of "milk of magnesia" (magnesia magma), is the only cathartic saline admissible in the presence of vomiting. The preparation is so mild in action that it is chiefly suitable as a laxative for infants, with whom 1 or 2 teaspoonfuls added to milk or other feeding daily may suffice as a temporary expedient. To the adult, tablespoonful doses may have to be given repeatedly before laxative effect is obtained. Magnesium oxid is likewise rather feeble in cathartic action, and is more useful as a gastric antacid than as a laxative, especially in view of the reputed danger of formation of intestinal con-

* This is the fourteenth of a series of articles on the pharmacology, physiology and practical application of the common laxatives and cathartics. The first article appeared October 18.

cretions, when it is used for a time in the large doses required for cathartic effect. When magnesium oxid is prescribed by the teaspoonful, its lightness should be borne in mind. Even the "heavy magnesium oxid," the only form that should be employed internally, does not weigh much more than 1 gm. (15 grains) per teaspoonful. True, 2.5 gm. (40 grains) are equivalent in magnesium contents to 15 gm. (240 grains) of magnesium sulphate; but the oxid is much feebler in action, as it lacks solubility and, of course, the sulphate ion. To children, magnesium oxid might be given in the following dosage:

For 6 months old, from 0.30 to 0.60 gm. (5 to 10 grains)
For 18 months old, from 0.60 to 1.30 gm. (10 to 20 grains)
For 3 years old, from 1.30 to 2.00 gm. (20 to 30 grains)
For 5 years old, from 2.00 to 3.00 gm. (30 to 45 grains)

The subjoined prescription yields a palatable administration form for this drug:

R: Magnesium oxid15 gm.
Fennel oil-sugar30 gm.
M. Label: One half of level teaspoonful two or three times daily.

Sodium phosphate is undoubtedly, next to magnesia, the least offensive of the cathartic salines. The taste is sufficiently like that of cooking salt to permit its administration in salt-free broth without the knowledge of the patient. It can thus be readily administered to a child. For bottle-fed infants, a dose of from 0.12 to 0.25 gm. (2 to 4 grains) may be added to each bottleful of milk. Dosage for children might range as follows:

For 6 months, from 0.30 to 0.60 gm. (0.5 to 10 grains)
For 18 months, from 0.60 to 0.90 gm. (0.10 to 15 grains)
For 3 years, from 0.90 to 1.30 gm. (0.15 to 20 grains)
For 5 years, from 1.30 to 2.00 gm. (0.20 to 30 grains)

For a child 3 years old this salt may be prescribed in the form of the following solution of actually delicious taste:

	Gm. or C.c.	
R Sodium phosphate	12/0	3iii
Syrup of raspberry.....	20/0	3v
Orange flower water to make.....	50/0	3ii

M. Label: Teaspoonful with water every two hours until evacuation is obtained.

As this is a fairly saturated solution, increase in dosage would be obtained by having the patient take a larger spoonful. For an adult, the dose of this solution would be a tablespoonful. However, adults take it readily in doses of from 2 to 8 gm. ($\frac{1}{2}$ to 2 drams) in a teacupful of water, as hot as can be borne. Such a dose might be administered once, twice or thrice daily, half an hour before meals; or else the effervescent sodium phosphate may be taken by the dessert-spoonful in half a tumblerful of cold water or lemonade.

For the bitter cathartic salines, cold effervescing solution is the best administration form. The effervescence diminishes their taste: chiefly, perhaps, in a physical manner. Innumerable gas bubbles are formed the instant the cold fluid charged with carbon dioxid comes in contact with the warm surface of the mouth. The tasteless gas, taking the place, to a large extent, of the salty liquid, protects much of the gustatory surface against excitation. Furthermore, carbon dioxid as well as coldness have a depressing effect on the excitability of the gustatory nerve endings. Imparting

effervescence to the dose is also of advantage for its effect on the stomach, chiefly because it expedites the passage of ingested material out of the stomach.² The sedative effect of the carbon dioxid on the gastric mucosa also lessens the nauseating tendency of these salts. These considerations enable one to understand why effervescent preparations are so prominent among the administration forms for soluble salines. It seems self-evident, however, that the administration of carbonated drinks should be avoided in patients with flatulent distention of the abdomen and in those suffering from dyspnea. Likewise is administration in effervescing form contraindicated in patients with cardiac enfeeblement. It is particularly obnoxious in dropsical patients with ascites.

All four available means of imparting effervescence to pharmaceutical products are made use of in the administration of these bodies.

In the preparation of the *Solution of Magnesium Citrate*, the most pleasant administration form for soluble cathartic saline, there is added to the sweetened and flavored fluid containing magnesium citrate and an excess of citric acid, just before inserting the stopper, a sufficient quantity of crystallized potassium bicarbonate to neutralize the acid. The stopper, having been securely fastened, retains the liberated carbon dioxid under pressure, so that on removal of the stopper, copious effervescence ensues. The dose of this solution for a vigorous adult is a bottleful (360 c.c., or 12 ounces). For persons presumably easily acted on, one half of the contents of the bottle may be given, and the balance kept in a cool place and well stoppered, to be administered in two or three hours if the first dose has not produced the desired result. Larger children will take a wineglassful of this solution with relish; and this dose may be repeated every two hours until a satisfactory evacuation has been obtained. Small children or infants should not be given this or any other effervescent medicament, as the unaccustomed appearance of the "spots" in the fluid frightens and repels them.

"*Scidlitz Powders*" (*Compound Effervescing Powder*) represent an ingenious method of obtaining an effervescing preparation of excellent keeping qualities. The effervescing ingredients (sodium bicarbonate and tartaric acid) are simply kept separate by being wrapped in powder papers of distinctive color—white for the acid, blue for the alkaline powder—to the latter of which are added 8 gm. (2 drams) of sodium and potassium tartrate. Just before taking, they are mixed in half a tumblerful of water. By having the water ice cold, and adding lemon juice and sugar to it, the dose may be made fairly palatable. One pair of powders is a rather mild aperient. Two pairs may be taken at one time, if required; or the dose may be repeated every three or four hours until the desired effect is obtained. A patient who is nauseated will probably not retain the whole dose given at once; but, when each of the powders is divided into fourths and this given in half a wineglassful of water every fifteen

2. This is the reason, for example, for the popularity of "soda water" during hot weather for water quenches thirst only while it is in the mouth and after it has left the stomach.

minutes, one may succeed in "settling" the stomach and producing an evacuation of the bowel at the same time.

Effervescent purgative salts are nothing more or less than a mixture of sodium bicarbonate and tartaric acid with the purgative saline—preferably sodium phosphate. All that is required for fair keeping qualities is that the ingredients be dry and be kept dry. Granulation is nonessential.

Finally, the saline may be added to carbonated water from a siphon bottle. In this manner, *magnesium sulphate*, the cheapest, most powerful, and most widely used of the salines, may readily be administered in its best disguise, namely, in form of ice-cold effervescing lemonade made without sugar, for the bitter-sweet taste is even more obnoxious than the bitter. Thus, a tablespoonful of Epsom salt may be mixed in a tumbler with a tablespoonful of lemon juice, a little cold water added for solution of the salt, and then the glass be half-filled with ice-cold carbonated water. Sucking a little lemon before, and drinking a large tumblerful of cold water immediately afterward are still further helpful in overcoming the disagreeableness of a dose of bitter salt.

In view of this abundance of satisfactory administration forms for salines, what justification is there for prescribing proprietary fancy-named products, whose only merit lies in clever advertising? An example of the result of the thoughtless recommendation of nostrums by physicians is "Sal Hepatica."³

MINERAL WATERS

Mineral waters are closely akin to nostrums in the manner in which many of them are exploited. For example, "Pluto Concentrated Spring Water," for which claims are made which in mendacity almost rival those of "patent medicines" in their palmy days, owes its activity to Glauber's salt, 50 per cent.; Epsom salt, 31 per cent.; cooking salt, 2.5 per cent., with calcium sulphate nearly 3 per cent., and a trace of magnesium carbonate.⁴ Does any rational-minded physician believe that he will get better or different results from this combination than he would from an analogous amount of either sodium sulphate or magnesium sulphate? Then why make the patient pay so much more for his "dose of salts"? Whenever physicians are as lavishly supplied with samples as they are with "Sal Hepatica" and "Pluto Water," let us remember that, aside from many other objections to them, somebody will have to pay a great deal more for the stuff than it is worth and resolve that it will not be our patients.

Experience, forced on us by the war, has shown that we can get along just as well—and, in point of fact, a great deal better—without such world-famed mineral waters even as "Hunyadi" or "Carlsbad."

While taking a mineral water at the springs adds the benefit of climatotherapy to that of pharmacotherapy, it is surely indisputable that whatever virtue is inherent in a mineral water taken at home is innate

in its constituents. An artificial combination of these cannot fail to be just as good. Indeed, it is much better; for the physician can then control the constituents in such a way as to make them more suitable to the individual for whom they are intended. For example: Carlsbad salt is a combination of approximately the following composition: sodium chlorid, 1 part; sodium bicarbonate, 2 parts; sodium sulphate, 4 parts. The combination of alkali with cathartic saline must be admitted to have peculiar virtues. For one thing, it is better borne by the stomach of most dyspeptics than is the simple saline. Furthermore, the alkali has certain therapeutic indications, the consideration of the details of which would lead us beyond the scope of this article, which at times, might well be met in a constipated individual by simultaneous administration of a purgative. The advantage of the possibility of varying the proportions in the salt combination to meet the special indication of these different cases is sufficiently obvious to require further discussion. More than this can, however, be accomplished. There is no reason to suppose that it is impossible to improve on "nature," which, in this case, is nothing but the fortuitous presence of certain salts in the strata of earth through which the water happened to pass. In case of the Carlsbad salt combination, for instance, a great improvement in taste can be secured by substituting sodium phosphate for the sodium sulphate, and sodium citrate for the sodium chlorid, as in this prescription:

	Gm.	℥ss
R Sodium citrate	15 0	℥ss
Sodium bicarbonate	30 0	℥i
Sodium phosphate	60 0	℥ii

M. Label: Teaspoonful in a cupful of hot water half an hour before meals.

This salt formula has secured as good results as have been obtained in suitable cases from Carlsbad salt, natural or artificial. A most important thing to be remembered in prescribing the salts of mineral waters is that the chief ingredient of mineral water is the water.

(To be continued)

Campaign Against Child Labor.—How hundreds of communities throughout the country have organized against child labor and illiteracy is told in a bulletin "Every Child in School" just issued by the Children's Bureau of the U. S. Department of Labor. This bulletin describes the methods and results of the "Back-to-School" and "Stay-in-School" campaigns carried on last year by forty-four states and the District of Columbia under the auspices of the Children's Bureau and the Council of National Defense. A larger proportion of these states have continued their efforts to stamp out child labor. As a result school time has been prolonged in many communities for boys and girls who might otherwise have had their education cut short. The "Back-in-School" and "Stay-in-School" campaigns have shown that in many places school attendance and child labor laws are not enforced. Many children of school age are in factories because there was not a sufficient number of attendance officers and factory inspectors to keep them in school and out of industry. In a single district an inspector reported 1,700 children as not having had a day of schooling. In many rural districts the children attend school only about half the time, and the hours for rural schools are very short. It is conditions such as these, the bulletin points out, that make the United States eighth instead of first on the list of civilized countries with regard to the proportion of literacy among its citizens.

RECENTLY DISCOVERED ASPECTS OF THE CAPILLARY BLOOD VESSELS

Recent investigations are conspiring to invest the blood capillaries with unexpected powers and correspondingly increased importance. Most of us have been taught to regard them as plastic vessels that permit the passage of waste or nutriment, as the case may be, through them by diffusion or other physicochemical processes. The capillaries, being devoid of a musculature such as is responsible for the changes in the caliber of the arteries, were assumed to be incapable of independent alteration of size, although they evidently respond passively to the greatly unlike volumes of blood driven into them at different times by the varying condition of the other parts of the circulatory system. Thus the capillary is well filled or empty, dilated or collapsed, according to the different masses of blood that reach it.

What has long been suspected regarding the motility of the capillaries in a few locations in the body has latterly become likely for many or all of them. These structures are known to have a formerly unsuspected nerve supply, which might be regarded as at least one prerequisite for independent contractile power. The existence of motility in nonmuscular cells, such as leukocytes, is familiar; hence, as Bayliss¹ has recently remarked, the absence of a muscular coat in the case of the capillaries does not warrant a denial of the possibility of active changes in caliber in the latter.

Professor Krogh² of Copenhagen has summarized considerable evidence which contravenes the prevailing conception that the blood is continuously flowing through the capillaries at rates that are determined solely by the state of contraction or dilatation of the corresponding arterioles. Under the old hypothesis, the dilatation of an arteriole will cause a rise of pressure in the corresponding capillaries, which will become passively expanded, to contract again by their own elasticity when the pressure is reduced. Today we seem, rather, forced to admit that these smallest vessels contain contractile elements of some sort within them-

selves and that they function especially in the direction of active dilatation. Thus the significance of a "capillary tone" can be understood.

The assumption of independent motility of the capillaries helps to explain the enormous variations in permeability that may be exhibited somewhere in the capillary region quite independent of any corresponding or coincident changes in general blood pressure, which have often been regarded as the impelling forces in the exchanges thus going on. In certain types of shock, for example, changes in the volume and concentration of the blood cannot be satisfactorily correlated under the older theories with the alterations of pressure in the circulation. The demonstration of independent activity on the part of the capillaries makes it easier to understand how blood may, as it were, disappear from the circulation. The capillary effect represented by the actively dilating vessels may actually overcome the usual effect of the contracting arterioles. Hereafter, therefore, it will be essential to know how and what substances act on the capillary mechanism, as well as their behavior toward the heart or the vessels equipped with contractile musculatures.

CARCINOMA OF THE APPENDIX

An English surgeon, Adams,¹ has recently commented on the fact that carcinoma of the appendix seems to be much less common in Great Britain than it is in the United States. He bases this statement on the observation that only four cases have been recorded among the 7,000 appendectomies that have been performed at St. Thomas' Hospital in London in the past seventeen years. This would give carcinoma of the appendix an incidence of only 0.05 per cent. in Great Britain, as contrasted with American figures which vary between 0.13 and 0.49 per cent.

Adams calls attention again to certain peculiarities of carcinoma of the appendix that distinguish it from most other forms of carcinoma. The explanation for the discrepancy between his figures and the American figures is quite clear, for he states in his article that routine microscopic examinations of the appendixes removed at operation were not made. This brings out the most important fact concerning carcinoma of the appendix, namely, that it is practically always an accidental finding. Figures such as those which have been published from the Mayo Clinic showing that nearly 0.5 per cent. of the appendixes removed were carcinomatous are due entirely to the fact that careful routine examination of all specimens is carried out. The fact that carcinoma of the appendix is usually an accidental discovery is due to certain peculiarities of the disease, the most important of which are the extreme slowness of its development and its comparative benignity. As a matter of fact, carcinoma of the appendix has practically never been diagnosed except on the operating

table or in the necropsy room. When symptoms are present, they are the symptoms associated with appendicitis.

The condition is interesting on account of the questions that it raises. Carcinoma of the appendix is perhaps the best illustration we have of the fact that the microscopic structure of a neoplasm is not always a safe indication of clinical malignancy. It emphasizes a point of view that is sometimes forgotten—the division of neoplasms into benign and malignant neoplasms is, after all, an arbitrary one. There are not a few instances of tumors that are structurally benign causing metastases and presenting other characteristics of malignant growths. There are instances of new growths with the microscopic structure usually associated with malignancy which fail to metastasize and even fail to invade neighboring structures. Carcinoma of the appendix also brings up another question, namely, whether vestigial structures are more likely to be the seat of neoplasm than organs that are still of value to the body. It is, of course, notorious that degenerative changes take place in the appendix with great frequency, particularly the so-called obliterative appendicitis, and it has been suggested that carcinomas of the appendix are associated with this obliterative appendicitis. Some pathologists, indeed, have doubted whether many of the so-called neoplasms of the appendix were true neoplasms. They have held that the changes which occurred were in the nature of an atypical epithelial growth, such as may occur with many inflammatory chronic conditions, rather than true malignant neoplasms. The subject is worthy of further and more careful investigation.

THE METABOLISM OF THE NERVOUS SYSTEM

Recent years have witnessed a marked change in the views held with respect to the metabolism of the nervous system. Formerly this tissue was not regarded as an active participant in those types of chemical change in the body for which the muscles have been preeminently noted. The products of such metabolism are excreted in the body in the respiratory gases and, in far smaller degree, in the urine. Augmented muscular activity is promptly followed by an increased output of carbon dioxide and water that is rarely so small as to escape detection. In all the experiments which have been conducted to discover analogous increments of waste products incident to the activity of the nervous system, only negative results have been recorded by the same method of investigation. When dietary factors and muscular performance have been essentially unchanged, the vigorous exercise of the higher nervous system, so far as this is possible by the conscious cerebration of intellectual effort, has never been observed to alter the metabolism of matter and energy of the body as a whole.

This is not strange, however, if the small bulk of the nervous system in comparison with the ever-functioning muscular tissues is taken into account. Small increments of output may fail of appreciation in the larger aggregate of waste from other sources. The conventional methods of study have left us in the lurch in the study of the possible metabolism of the small, yet highly valuable portion of the body represented by the brain and its nervous appendages. Here the study of the isolated tissue, particularly by micro-analytic methods, has thrown new light on the functioning of those structures which were scarcely believed to exhibit the same order of energy transformations and material changes that are the conspicuous accompaniments of activity in muscles and glands. The investigations of Tashiro, in particular, at the University of Chicago, have demonstrated that nerve fibers have a metabolism as active as that of any tissue in the body. Ganglions appear to have a somewhat higher rate than the nerve fibers. Such estimations as have been made of the oxygen consumption of the brain—an index of its chemical exchanges—place it at a figure decidedly greater than that of skeletal muscle.

Evidently, then, the nervous tissues are not devoid of a vigorous "internal respiration." For the activity of the muscles, carbohydrates are now looked on as the preferred source of energy. Recent studies by Hirschberg and Winterstein¹ at Rostock have shown that the nervous system likewise can utilize sugars if one may judge from their disappearance from solutions brought into intimate contact with surviving nerves. There may also be some metabolism of nitrogenous components detectable even in the small portions of tissue that have been examined in this way by these observers.²

Even more unexpected, however, is the evidence presented for the metabolism of the lipid components of nerves in the presence of oxygen.³ This disintegrative change can be retarded by the presence of sugars, which seem to exert a "sparing" action on the lipoids. The products of the oxidative breakdown of the nerve lipoids is not yet known. This evidence of the possible involvement of the lipoids in nerve metabolism is in harmony with the contention of Mathews,⁴ who regards the medullary sheath as probably nutritive. He has pointed out that the brain contains no glycogen or neutral fat. Since the nerve cells must have a good supply of raw material for such active metabolism as the experiments on tissue respiration indicate them to have, there is no apparent reason why the abundant lipoids should not be drafted into use.

RENAL GLYCOSURIA

Interest in the subject of so-called renal diabetes has been greatly increased since estimations of the sugar content of the blood have become more commonly and easily carried out. The current conception of the condition referred to involves a glycosuria that occurs when the blood sugar is not significantly increased in amount, that is, when hyperglycemia cannot be demonstrated. The analogy of experimental phlorizin diabetes in which there is likewise a liberal renal output of sugar without any increase in the percentage content of sugar in the circulating medium of the body has frequently been referred to. In either case it has been assumed that the anomaly leading to the "renal glycosuria" resides in the kidneys, and that the disease is of renal rather than general metabolic significance.

A careful student of the subject has stated that "clinically, it is dangerous to make a diagnosis of renal diabetes until the patient has been under observation for several years."¹ This can scarcely be true in those instances in which the examination of the patient is controlled and supplemented by accurate and adequate laboratory data. Otherwise we should hesitate to refer to cases of "renal glycosuria" studied with exceptional care by Allen² and his co-workers in U. S. Army General Hospital No. 9 at Lakewood, N. J., where a diabetic service was instituted. Observation of three cases of the renal type as compared with thirty-seven cases of true diabetes in military service, and the increasing number of reports in the literature, as the determination of blood sugar content increases, led the army investigators to conclude that "renal" glycosuria is not as rare as once supposed, and probably is much commoner than other anomalies, such as pentosuria or levulosuria. It has by no means been definitely established, however, that the excreted sugar in "renal" glycosuria is in every instance identical with the common diabetic sugar, glucose.

As has been noted in earlier cases, no fixed relations were observed between the sugar in blood and urine. The renal excretion does not necessarily serve to maintain a low level of blood sugar. The output is not always higher with high than with low blood sugar. According to Allen's observations, the sugar excretion seems to be determined by the supply of available carbohydrate, especially preformed, but also to less degree by the potential carbohydrate of protein. The fat ration and total metabolism, which are important in true diabetes, are probably without influence.

No hypothesis that has been suggested thus far serves to explain satisfactorily the genesis of a condition of glycosuria apparently independent of hyperglycemia. As Allen and his co-workers point out, it is not yet proved that the abnormality lies in the kidney,

or that it consists merely in a lowering of the normal threshold of sugar excretion. It is possible that cases differ in kind as well as degree, and that a group of anomalies have heretofore been included under this name. Fortunately, however, the prognosis in the persistent condition described is very favorable, thus standing in striking contrast with what so commonly obtains in true diabetes mellitus. Perhaps "renal" glycosuria will be found to represent only an exaggerated instance of the "glycuresis" which Benedict has described as occurring in normal man and leading to a minute though commonly present content of sugar in the urine.³ In any event, now that the greater frequency of a relatively harmless renal glycosuria is appreciated, it will henceforth be more essential than ever before to make a differential diagnosis with the utmost accuracy that present clinical methods permit. One type of glycosuria may benefit greatly by suitable dietary restrictions, whereas the other rarer form does not require comparable personal sacrifices.

SOME ASPECTS OF WAR EDEMA

The people of the United States were fortunate, during the past five years, in averting more than one disaster that has overtaken the inhabitants of some European countries. They have escaped the dangers of various infections; they have been far removed from the nervous depression and accompanying harm; and however restricted they may have been in diet, real physiologic deprivations of necessary food have not been felt to any considerable extent. Hence we must look abroad for direct evidences of the diseases that unusual deprivations have created or brought into prominence. "War edema," known in Napoleon's campaigns and sometimes observed in institutions in which restrictions in living conditions are enforced, was emphasized as a disease entity of widespread distribution in the last three years of the war.

The pathologist is wont to dwell on the special or immediate causes of edemas, on cardiac or renal factors, on inflammatory involvements, on neuropathic and even hereditary features that precede the symptoms. The phenomena of war edema must be related to antecedent causes which still need to be recognized clearly and determined with scientific accuracy before the complete etiology can be written. An unusually comprehensive investigation reported by Schittenhelm and Schlecht⁴ of Kiel, as the result of elaborate studies amid an abundance of German cases, may assist in clearing up some of the disputed points. Aside from the somewhat differing symptoms of pain, fatigue, skin

disorders, localized edema, etc., there is unanimity in the finding of a greatly lowered condition of general nutrition. The subcutaneous adipose tissues are always entirely depleted; the musculature may be reduced to an exquisitely atrophic state, and the vigor of the subject is correspondingly diminished. Resistance to infectious invasions of the skin naturally decreases, leaving all sorts of cutaneous and subcutaneous disorders in its wake.

The recent tests in many illustrative cases show that the excretory capacity of the kidney for water and salt is not essentially decreased; hence it appears that edema of this type is not of renal origin. Not only this fact, but the entire symptomatology suggests that war edema represents an involvement of the entire organism in which the edematous features are only a single manifestation. The blood plasma has been found to be greatly diluted, as if there were a decided depletion of protein in the body. The restoration of the blood in respect to protein content is accordingly one of the early manifestations of feeding albuminous foods to edema patients.

Depletion of the body's reserves of nutriment furnishes the keynote to the pathogenesis of war edema. For a long time this loss of substance may not be apparent, because edema fluids replace the losses and, by keeping up the weight and contour of the body, simulate satisfactory nutrition. Chemical investigations tell the real story. Fats, lipoids and glycogen vanish; the blood is poorer in protein—not merely diluted with water; the composition of its corpuscles even is altered. Everywhere there is depletion; but this by no means implies that loss of calories per se is responsible. Here we come into the domain of controversy. Is war edema to be regarded as the outcome of severe undernutrition in general, or is it the expression of a specific deprivation, such as a lack of protein or fat or vitamins? At present it cannot be gainsaid that all of these factors may be involved. The admittedly specific deficiency diseases, such as beriberi, frequently include manifestations of edema, but it must be borne in mind that lack of vitamins is not infrequently associated with diminished food intake in general and with consequent depletion of other body reserves. Whether the organism requires a minimum of fat as truly as a quota of protein below which nutritive disaster is sure to be encountered remains to be seen. Aron⁵ has lately contended that fats as such furnish constituents, aside from so-called fat-soluble vitamins, indispensable to the body. In the past much has been said about overfeeding of protein. The diet of war-time shortage abounds in carbohydrate which forms the basis of the intake of those compelled to live on restricted rations. May there not be an ill effect from undue increments in starch and sugar—an excess of carbohydrate?

These and other questions vigorously present themselves for consideration in connection with the mysterious war disease. As for the edema itself, we may quote the suggestion of Schittenhelm and Schlecht that scanty and one-sided diets may lead to imperfect make-up of the tissues—which includes that of the capillaries wherein the anatomic cause of the edema is to be sought. Arguing that even the war-time diets are not likely to be so utterly devoid of vitamins as to lead to the specific deficiency diseases classed as avitaminoses, the German clinicians are rather inclined to incriminate shortage of other food factors or overabundance of carbohydrate or both combined. Such dietary conditions are known to lead to comparable nutritive disorders, for example, the "Mehlnährschaden," in children. At any rate, the fact that it is possible for large masses of men to live and carry out their normal employment—as happened in Germany—on a much scantier diet than that to which they were accustomed can no longer be cited in support of the once widely quoted statement that "this state of economical nutrition seems to be without danger to health even when extended over several months."⁶

Current Comment

LEST YOU FORGET—"A REMINDER"

Three weeks ago a green slip, to be used in remitting subscriptions and Fellowship dues for 1920, was inserted in *THE JOURNAL*. This slip was circulated in place of statements addressed to individual subscribers and Fellows. A large number have returned the slips with their remittances, and their cooperation has resulted in a large saving for the Association in postage. For the convenience of those who have not yet made the remittance, another slip is inserted in this issue. Moreover, it will remind those who may have made use of the previous slip that they may take advantage of the clubbing offers announced on the colored insert in the front advertising section of this number.

PUPILLARY CHANGES IN SYPHILIS

Stress has been placed for many years on the importance of pupillary changes in the detection of latent syphilis and of certain diseases of syphilitic origin, such as locomotor ataxia and general paresis. These pupillary changes have usually been described as symptomatic of the late stages of the disease. Recently Nicolau⁷ has called attention to the fact that pupillary changes are common in the early stages of syphilis. Thus, inequality of the pupils particularly may occur even before the appearance of the skin manifestations of secondary syphilis. Nicolau associates it with the early changes in the central nervous system which are

evidenced by changes in the cerebrospinal fluid obtained by lumbar puncture. He recognizes the well known fact that pupillary inequalities are not infrequent in normal persons, and states that approximately 3 or 4 per cent. of normal persons show such changes. He maintains, however, that syphilitic persons show pupillary inequalities in the early stages of the disease in a much higher percentage of cases. At least 10 per cent. of early syphilitics were found to have marked pupillary inequality, and 70 per cent. showed slight pupillary inequality. While the value of these observations is somewhat impaired by the comparative frequency of pupillary inequality in normal persons, they are not without interest, and the sign will doubtless be of some value in conjunction with other signs. In doubtful cases of any disease the diagnosis is usually reached by combining many symptoms and signs which in themselves may be trifling.

COLD STORAGE TESTIMONIALS

The law which limits the length of time that food products may be kept in cold storage could with advantage have its scope extended to include "patent medicine" testimonials. Physicians recently received through the mails—at a time when the mails were frightfully congested with Christmas business—a sixteen page pamphlet sent out in a plain envelop as First Class Matter. The caption of the pamphlet reads: "Cough and Its Treatment in Pulmonary and Laryngeal Tuberculosis: By Henry Levien, M. D., While Medical Director and Physician-in-Charge of the Liberty Sanitarium, Liberty, N. Y. From the *Buffalo Medical Journal*." The pamphlet is devoted to the alleged virtues of that dangerous and widely advertised nostrum, "Glyco-Heroin (Smith)," whose more recent and less descriptive name is now "Glykeron." Physicians might assume, and doubtless will assume, from the pamphlet that this reprint represents a recent pronouncement on the subject with which it deals. The facts are that the "Liberty Sanitarium" has, apparently, been out of existence for at least fifteen years, while the article itself originally appeared more than eighteen years ago—September, 1901. One of many physicians who sent in the copies received, called attention to the fact that he had left the address to which the pamphlet was directed, more than six years ago. Even at that, the mailing lists of the concern that sells this heroin-containing nostrum are more than twelve years ahead of its "clinical reports."

Medicated Soaps.—Medicated soaps are for the most part a snare and delusion so far as any increased germicidal action is concerned. In fact, the addition of carbolic acid, bichlorid of mercury, and other substances which have the property of combining chemically with the soap seems actually to diminish the disinfecting value of the substance. As a rule a very small quantity of the disinfecting substance is added to the soap, and when we call to mind what an exceedingly small quantity of soap is generally used for the ordinary washing of the skin and the further dilution of this small amount by the water used it is easy to understand that medicated soaps as ordinarily applied cannot have an energetic disinfecting action.—Rosenau, "Preventive Medicine and Hygiene."

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Child Hygiene Bureau Established.—The Birmingham Health Department, December 1, established a bureau of child hygiene. This bureau will undertake to teach child culture and to act in an advisory capacity to parents and to the other branches of the health department.

Infirmiry to Be Remodeled.—A permit was issued, November 17, for the Fraternal Hospital, Birmingham. The present building of the McAdory Infirmiry is to be remodeled, and additions made until the capacity of the institution will be 152 beds. Dr. Willington P. McAdory, Birmingham, is president, and Dr. John H. Stephens, Hendersonville, secretary of the new hospital organization, which is capitalized at \$125,000.

Personal.—The Bureau of Venereal Disease Control of the State Board of Health has arranged with Dr. Hugh L. Appleton, Gadsden, to conduct a cooperative clinic in Gadsden.—Dr. Lloyd Noland, Birmingham, superintendent of health of the Tennessee Coal and Iron Railroad Company, was the guest of honor at a banquet, held December 13, in Birmingham, tendered by the district physicians and other officials of the department of health as a tribute to the achievements wrought by Dr. Noland in the organization of that work. Dr. Grosbeck Walsh, Birmingham, presided as toastmaster.

New Officers.—The Mobile Medical Society at its meeting, December 6, elected Dr. Alfred E. Maumenee, president; Dr. William H. Oates, vice president; Dr. Willis W. Scales, secretary, and Dr. Edly W. Cawthon, Plateau, treasurer.—At the annual meeting of the Jefferson County Medical Society in Birmingham, December 3, Dr. E. Marvin Mason, Birmingham, was elected president; Dr. Robert E. Cloud, Ensley, vice president, and Dr. Gaston W. Rogers, Birmingham, secretary-treasurer.—Montgomery Medical Society at its annual meeting elected Dr. Milton B. Kirkpatrick, president; Dr. Frederick F. P. Boswell, vice president; Dr. Abraham Tumper, secretary, and Dr. Forney C. Stevenson, treasurer.

CALIFORNIA

Orthopedic Hospital School to Be Established.—To meet the physical, educational, and vocational needs of crippled children, an orthopedic hospital school is to be established by the Los Angeles Orthopedic Foundation. The site for the proposed institution has been donated to the foundation by John Bruckman, in addition to which \$60,000 has thus far been donated.

New Officers.—At the annual meeting of the San Diego County Medical Society, held December 9, Dr. Lyell C. Kinney was elected president; Dr. J. Perry Lewis, vice president; Dr. George B. Worthington, secretary, and Dr. Mott H. Arnold, secretary-treasurer, all of San Diego.—Sonoma County Medical Society at its annual meeting, held at Petaluma, December 11, elected Dr. Fred O. Butler, Eldridge, president; Dr. William C. Shipley, Cloverdale, vice president; Dr. Nils R. H. Juell, Santa Rosa, secretary, and Dr. Reuben M. Bonar, Santa Rosa, treasurer.

Lecture on Psychology and Health.—Prof. George M. Stratton of the University of California is giving a series of lectures during January and February on psychology and health. The lectures are being given in Emann-El Auditorium, 1337 Sutter Street, San Francisco, on successive Friday evenings, beginning, January 9. The lectures will deal with the modern aspects of the relation of psychology and the principles of health and practice of medicine, with diseases of the mind, insanity, hypnotism, and with multiple topics on personality and other subjects. They will be scientific in essence, but will not be technical in character.

Personal.—Dr. Eugene A. Hensel, San Diego, is under treatment in St. Joseph's Hospital.—Dr. Henry P. Newman, San Diego, who has been ill for several weeks, has recovered.—Dr. Paul W. Newcomer, Pomona, has been elected president of the Pomona Valley Medical Association, and Dr. William H. Eaton, Pomona, secretary.—Dr. Henry G.

Brainerd, Los Angeles, has been elected president of the Psychological Association of California.—Neal Naramore Wood, Major, M. C., U. S. Army, has been appointed first assistant superintendent of charities and medical director for the department of charities of the county of Los Angeles.

DISTRICT OF COLUMBIA

New Building for Society.—It is announced that during the next few weeks ground will be broken on a lot which has been purchased on M Street near Connecticut Avenue for the new building for the Medical Society of the District of Columbia.

Personal.—Dr. J. Ward Mankin, resident surgeon of Emergency Hospital, Washington, for two years, has resigned.—Dr. John F. Rooney, United States Public Health Service, was shot three times by a former soldier and a patient at Providence Hospital. Although the wounds are serious, Dr. Rooney is expected to recover.

New Officers.—The Medical Society of the District of Columbia, at its meeting, December 4, elected the following officers: president, Dr. Francis R. Hagner; vice presidents, Drs. Virgil B. Jackson and A. Frances Foye; recording secretary, Dr. Henry C. Macatee; corresponding secretary, Dr. J. Russell Verbryke, Jr., and treasurer, Dr. Edward G. Seibert.

GEORGIA

New Officers of Medical Board.—At the annual meeting of the state board of medical examiners, Dr. Jarrett W. Palmer, Ailey, was reelected president; Dr. Alfred F. White, Florilla, vice president, and Dr. Charles T. Nolan, Marietta, secretary-treasurer.

Personal.—The office of Dr. Amos C. Smith in the First National Bank Building, Elberton, has been destroyed by fire.—Dr. William E. Wood, Dalton, has been elected mayor in a hotly contested race with Dr. Jesse G. McAfee.—Dr. Taylor Lewis, Americus, sustained serious knife wounds of the abdomen and face in an affray recently.

Hospital Notes.—The Cheston King Sanitarium, Atlanta, has been secured by the United States Public Health Service which will use the institution as an emergency hospital and a clearing house for soldiers, sailors, marines and civilian employees of the government, through which patients will be sent to the various public health hospitals in the Southeast.

ILLINOIS

Personal.—Dr. Charles B. Caldwell, assistant superintendent of the Peoria State Hospital, South Bartonville, has been appointed superintendent of the Lincoln State School and Colony, succeeding Dr. Thomas H. Leonard.—Dr. Dudley B. Reid of the University of Chicago was elected president of the National Council of the American Physical Education Association at its annual meeting in New York City, January 1.

MAINE

New Officers.—At the annual meeting of the Penobscot County Medical Society, held in Bangor, the following officers were elected: Dr. William E. Fellows, president; Dr. Jarvis B. Wood, vice president, and Dr. Harry D. McNeil, secretary-treasurer, all of Bangor.

New Hospital Wing Under Construction.—A new wing to the Augusta General Hospital is being built, and will be ready for occupancy in March. The new building will be three stories and a basement in height, of steel and tile construction, 96 feet long and 40 feet wide, and will have three operating rooms on the third floor.

MARYLAND

Accident to University President.—Dr. Frank J. Goodnow, president of Johns Hopkins University, who suffered a fracture of the leg, January 11, is reported to be resting comfortably.

Whisky to Hospitals.—Every hospital and charitable institution in Baltimore will be given a generous quantity of whisky by Mrs. William Lanahan, owner of the wholesale liquor house of William Lanahan & Sons, who has announced that the entire stock in the warehouse will be distributed among hospitals and institutions.

Vaughan on Sanitation.—At a lecture before the members of the Johns Hopkins University School of Hygiene and Public Health, Dr. Victor C. Vaughan, professor of hygiene

and physiologic chemistry at the University of Michigan, Ann Arbor, spoke at length on the influenza epidemic of 1918 and sanitation, expressing the belief that the limit of modern sanitation had been reached.

In Memory of Dr. Osler.—A joint meeting of the Medical and Chirurgical Faculty and the Book and Journal Club of the faculty was held at Osler Hall, January 13. This meeting was called in memory of the late Sir William Osler, and addresses were made by Dr. Lewellys F. Barker, Dr. Harry Friedenwald, Dr. John Ruhräh, all of Baltimore, and Dr. Francis R. Packard, Philadelphia.

Personal.—Dr. Robert H. Riley, Cumberland, has been appointed to the state board of health as chief of the bureau of communicable diseases of the state department of health. Dr. Riley was formerly chief bacteriologist of the health department of Oklahoma, and his affiliation with the local health department came as a result of a trip he made here to study public health administration methods.

Pathological Building Burns.—The Pathological Building of the Johns Hopkins Hospital group, the professional workshop of Dr. William H. Welch, was wrecked by fire, January 12. It is said that none of the valuable specimens was lost, nor were any of the records of research work damaged. The fire necessitated the removal of twenty colored women patients from Ward O, but the patients in the maternity ward remained in their beds. Great credit is to be given to the nurses and physicians for their presence of mind in this emergency.

War on Social Evil.—To carry on active warfare against social evils and diseases, the Maryland Social Hygiene Society has opened headquarters in the Hoen Building, Baltimore. Dr. Hugh H. Young, Baltimore, has been elected president of the society and the other officers and the board of directors include many of the leading men of Baltimore. Legislation, law enforcement, thorough investigation of existing conditions, protective measures, urging the proper disposition of offenders by means of probation, commitment to institutions or custodial care, recreation, education and medical attention are among the activities planned by the organization. The association, which is the fusion of all the unofficial organizations of the state which have been combating social disease, will act as a clearing house in diffusing knowledge on social health and in conducting vigorous attacks on vice.

Raid on "Associated Doctors."—Through an exposé in the *Evening Sun*, the offices of the "Associated Doctors" which were raided by detectives and all paraphernalia used by them, including the widely advertised intravenous injection outfit and the fluoroscope and roentgen-ray apparatus, found to be imitations, were sent to detective headquarters. J. Newbold Kirk and G. G. Payne escaped arrest only because they had left the city, following the exposé in the newspaper. The attention of the police board was directed to the "Associated Doctors" by Dr. Herbert Harlan, Baltimore, president of the state board of medical examiners. Subsequent investigation showed that most of the work in the office was done by a registered physician, after an extensive door-to-door advertising campaign had been made. It is intimated at police headquarters that criminal action will be brought against the "Associated Doctors."

New Hospital Opposed.—Protests have been issued by persons interested in the South Baltimore General Hospital to the people of South Baltimore, Brooklyn, and Curtis Bay against the establishment of a competing hospital in the section from which the South Baltimore General Hospital draws its patronage. The protestants set forth that to care for the medical and surgical cases developing in the industrial district of South Baltimore, Brooklyn and Curtis Bay, the South Baltimore Eye and Ear Hospital was reorganized as the South Baltimore General Hospital and was thoroughly equipped to care for all kinds of injuries and diseases, supplied with a staff of trained physicians and nurses and is prepared to give this industrial district every possible advantage of modern hospital service. If the patronage of this territory is divided and the field occupied by a competing institution, it is apparent that instead of one institution being an assured success and constantly improving, two institutions could barely keep their heads above water.

Southern Sociological Congress.—The Southern Sociological Congress, which has headquarters in Washington, D. C., held its annual conference at the Medical and Chirurgical Faculty Building, Baltimore, January 6 and 7. The program for the opening session included as speakers Henry E. Jackson of the United States Bureau of Education and

Congressman S. D. Fess of Ohio; the subject under discussion was American citizenship. Judge Joseph A. McCulloch presided at the conference. Three sessions were held on January 7, and these were followed by a dinner at the City Club. The aim of the congress is to promote health, justice, patriotism, and training for citizenship, and to teach the sacredness of law both as to person and property, as well as to foster loyalty to home, church and government. It also aims to unite the religious, educational, civic and industrial factors of the South in a general movement to promote the welfare and conservation of human life. Its plan has been to accomplish the coordination of church and school so that the greatest benefit may be derived from both.

MASSACHUSETTS

Physician Decorated.—Dr. Charles S. Butler, Boston, has received from the French government the Cross of the Legion of Honor in recognition of his service to wounded French soldiers.

New Hospital.—A new building is to be erected for the Baptist Hospital, Boston, at a cost of about \$500,000. The funds for the new building came from the estate of Mrs. Samuel N. Brown.

Personal.—Dr. Irwin H. Neff, formerly superintendent of the Foxboro State Hospital and for the past five years superintendent of the Norfolk State Hospital, Boston, has been made head of the Oak Grove Hospital, Flint, Mich.

Society Offers Reward.—The Essex South District Medical Society, December 27, offered a reward of \$1,000 for information leading to the arrest and conviction of the person or persons who assaulted Dr. Hamlin P. Bennett, Lynn, December 24.

Banquet to Cabot.—The trustees of the New England Baptist Hospital gave a farewell banquet at the Hotel Vendome, Boston, January 3, to Dr. Hugh Cabot, head of the surgical staff of the Baptist Hospital for twenty years, who had accepted the post of head professor of surgery in the University of Michigan, Ann Arbor. Tributes to Dr. Cabot were paid by Col. Edward H. Hackett, Dr. George S. C. Badger, Boston, and Walter I. Badger, Albert H. Curtis, and others.

Honor to Sargent.—In recognition of his fifty years of continuous service in the physical training field, a banquet was given by the Sargent School Alumni Association to Dr. Sargent at the Hotel Vendome, Boston, December 27, at which many prominent educators, including Dr. Charles W. Eliot, professor emeritus of Harvard University, gave testimony that the untiring efforts of Dr. Sargent had resulted in making educational leaders throughout the world realize the value of physical education for children and college students. At the close of the evening a testimonial volume containing articles written in eulogy of his work was given Dr. Sargent.

Committee on Public Health.—This committee of the Massachusetts Medical Society has recently initiated several important movements in promoting the activities in the interest of which it was created. In addition to furnishing to the county medical societies speakers on subjects of preventive medicine, hygiene and public health, it has each year conducted a convocation on public health in which it has secured the cooperation of the United States Public Health Service, the Massachusetts State Department of Health, and the Massachusetts Association of Boards of Health. Two of these health convocations have been held in Boston, and recently a third was held at Springfield. The program for the Springfield convocation shows a wide range of subjects, including the state health program, personal and school hygiene, industrial hygiene, diet, special disease problems, and sanitation. The registration at these meetings has averaged about 225 people from over fifty cities and towns. These conferences have been attended not only by physicians, but also by health officials, public health nurses, and others professionally interested in public health. This committee consists of Dr. Enos H. Bigelow, chairman; Dr. Annie Lee Hamilton, secretary, and Drs. Edmond F. Cody, Victor Safford and Roger J. Lee.

NEW YORK

Personal.—Dr. Edward F. Brush has retired from office after serving eight terms as mayor of Mount Vernon.—Dr. Edward W. Mulligan, Rochester, was chosen director of reorganized Base Hospital No. 19, December 15.

New Officers.—At the annual meeting of the Monroe County Medical Society held in Rochester, December 16, Dr. Emory W. Ruggles was elected president; Dr. George H. Gage,

vice president; Dr. Benedict J. Duffy, secretary, and Dr. Irving E. Harris, treasurer, all of Rochester.

State Society Meeting.—The annual meeting of the Medical Society of the State of New York will be held in New York City, March 23 to 25. The house of delegates will meet at the New York Academy of Medicine, 17 West Forty-Third Street, March 22. The scientific sessions will be held on the second floor of the Waldorf-Astoria, and the third floor of the Hotel McAlpin. A section on neurology and psychiatry will be inaugurated on March 23. There will be an open meeting of the society at the Hotel Pennsylvania, March 23, which will be followed by the president's reception. The annual banquet will be given, March 24, in the ballroom of the Waldorf-Astoria.

Governor Smith Advocates Public Health Centers and Industrial Insurance.—Governor Smith, in his annual address to the legislature, recommends liberal provision for the department of health and redistricting the state so that each community can support a proper health administration. He expresses the view that the time has come when there should be some plan of reorganization within the counties themselves under the supervision of the state authorities. He urges the establishment throughout the state of an adequate system of public health centers, in conjunction with local health activities, where the necessary public health supervision can be provided for all classes of the population. He believes the state should subsidize local health efforts and thus bring about a coordination of public and private health facilities so that every health center could command the services of a full-time health officer and the necessary public health nurses. He reiterates his belief in the principle of compulsory health insurance for industrial workers. He says that legislation carrying this principle into execution can be so drawn as to safeguard the interests of the medical profession.

New York City

Harvey Society Lecture.—The sixth lecture of the Harvey Society Series will be delivered, January 24, by Dr. Carl Voegtlin, professor of pharmacology, United States Public Health Service, on "Recent Work in Pellagra."

New York's Banner Health Year.—Dr. Royal S. Copeland, Health Commissioner, announces that the death rate for 1919 is the lowest recorded in the fifty-three years that the Health Department has been organized. The death rate for the year 1919 was 12.39 per 1,000 population, as compared with a rate of 16.71 for 1918, and 13.94 for the five-year period from 1913 to 1917, inclusive.

Personal.—Dr. Simon Flexner of the Rockefeller Institute for Medical Research was elected an associate member of the Société de pathologie exotique, December 10; of the Société royale des sciences médicales et naturelles, December 1; and of the Société belge de biologie, December 6; and was also made a corresponding member of the Bataafsch Genootschap der Proefondervindelijke Wijsbegeerte, of Rotterdam, December 22.—Dr. Phoebeus A. Levene of the Rockefeller Institute for Medical Research was elected an associate member of the Société royale des sciences médicales et naturelles, Brussels, December 1.—Dr. Joshua H. Leiner has been appointed adjunct attending neurologist to Lebanon Hospital.

Scabies in New York.—The health department reports that in certain parts of the city there has been a slight increase in the prevalence of scabies. Investigation shows that in a number of families in which cases have been found there have been returning soldiers and it is thought that this may account for the infection. The average number of cases reported for the year 1918 is much lower than for the preceding five years, while the total for the first three quarters of 1919 is within 194 cases of the total for 1918. The reports of all cases of scabies among schoolchildren are being carefully verified, and home visits are made by the school nurses for the purpose of ascertaining conditions and giving advice. Patients with scabies not under effective medical treatment are excluded from school.

Health Department Regulates Heating of Buildings.—At a meeting of the board of health, in December, 1919, Section 225 of the Sanitary Code was amended so that it shall be the duty of every person who has contracted or undertaken to furnish heat for any building or portion thereof, occupied as a home or place of residence of one or more people, or as a place of business, to furnish heat for every occupied room in such building so that a minimum temperature of 68 F. may be maintained therein at all times between the hours of 6 a. m. and 10 p. m. In the absence of a contract the owner, agent or lessee is deemed to have contracted or

bound himself or herself to furnish heat in accordance with the provisions of this section.

Association for the Prevention and Relief of Heart Disease.—This organization, recently installed in its new headquarters at 325 East Fifty-Seventh Street, is engaged in furthering the establishment of dispensary classes in many of the city hospitals for workmen with crippled hearts. It also seeks the opening of more convalescent homes to patients with the milder types of heart disease and the founding of institutions for the continued care of permanent invalids from the same cause. The association has recently issued a pamphlet showing that there were, according to the statistics of the health department, 10,682 deaths from heart disease in this city in one year, while during the same period tuberculosis in all its forms caused 9,622 deaths and cancer 4,702. This serves to call attention to the importance of heart disease as a cause of disability and death. The pamphlet states further that not less than 25,000 schoolchildren in this city have permanently damaged hearts. The association is endeavoring to disseminate in popular form some of the facts with reference to heart disease and the need of treatment as has been done in regard to tuberculosis.

NORTH CAROLINA

Personal.—Dr. Sylvester Utter, Crab Creek, is reported to be in a critical condition at the Patton Memorial Hospital, Hendersonville, as the result of a gunshot wound accidentally received while hunting.

Malaria in Goldsboro.—A recent survey has shown that approximately 25 per cent. of the population of Goldsboro are suffering from malaria in some form, and the city with the assistance of the state and federal health authorities is beginning an antimalarial campaign.

OHIO

Trachoma Surveys.—The schools of Hamilton are being surveyed for trachoma. When the schools closed for the Christmas holidays, about 3,900 pupils had been examined and 104 cases of trachoma had been found. When the survey is completed a clinic will be held by the U. S. Public Health Service and the state department of health. The survey of schoolchildren of Ross County for trachoma has been completed. The work was done by Dr. Rose Hopkins, assistant epidemiologist, state department of health, in cooperation with the local chapter of the Red Cross. Arrangements are now being made for a trachoma clinic to be held in Chillicothe some time in January.

Personal.—Dr. William G. List, Cincinnati, assistant superintendent of the Cincinnati General Hospital, has been appointed superintendent of the Minneapolis City Hospital, succeeding Dr. Herbert O. Collins, resigned. Drs. James D. Parker and Carl R. Knoble have been made members of the Sandusky board of education. Dr. John E. Mongor, Columbus, state registrar of vital statistics for four years, has resigned and has been succeeded by Dr. Ulysses G. Murrell, Wilmington. Dr. Willard C. Rank, Newark, who has been ill with septicemia in Mount Carmel Hospital, is reported to be convalescent. Dr. William R. Keller, Dover, has been elected commander of the Dover Post, No. 205, American Legion.

Legislature Amends Hughes Health Act.—The same legislature which adopted the Hughes act during the first part of their 1919 session has reconsidered its action and replaced it by the Griswold bill, which has now passed both houses and awaits the signature of the governor to become a law. The Supreme Court of Ohio, in a decision affecting another law, decided that the cities of Ohio could not be classified for purposes of legislation. This decision rendered it necessary to amend the Hughes act, as it classified cities as over and under 25,000 population. The legislature further amended it by removing the civil service provisions, by providing for whole or part time health commissioners, and by making the employment of nurses optional. Under the provisions of the new bill, cities may employ any one as a health officer, but in general health districts the health commissioner must be a licensed physician. The bill still permits counties and cities to have real health organizations and to do effective health work, and is a considerable advance over the old township and village law. The opposition to the Hughes act came largely from the rural districts and was based on the expense of the new system. Two hundred and seventy-six applicants from twenty-five states took the state civil service examination for district health commissioners under the

Hughes act. Candidates were just about to be called to Columbus for a personal interview when the examination was called off on account of the action of the legislature.

PENNSYLVANIA

Tuberculosis Home Opened.—The Hackett Home, the new building for tuberculous women at Norristown State Hospital, was dedicated, January 7. This building, containing wards, private rooms, special observation rooms and sun parlors, was erected at a cost of \$15,000. Dr. Jessie M. Peterson, Norristown, is in charge and under her is a staff of thirty nurses. The building will accommodate about 200 patients.

Personal.—Dr. Claude P. Brown, Ambler, Major, M. C. U. S. Army, has been made commander of Post 125, American Legion, Ambler. Dr. Albert H. Wilkinson, Wilkes-Barre, has been elected medical superintendent of the Roper Hospital, Charleston. Dr. Samuel B. Horning, Cooleville, has announced his retirement from the practice of medicine, and will spend the rest of the winter in Florida. Dr. Joseph Scattergood has been appointed local surgeon of the Pennsylvania system at West Chester, succeeding Dr. Percy C. Hoskins, deceased.

Philadelphia

Food Demonstration at Dietetic Center.—January 6, the dietetic center connected with the Jefferson chest department for nurses and social workers held an open demonstration of cooking and nutritious foods for mothers of the district.

Health Department Advisory Group Named.—Director Clinton L. Furbush of public health and charities, January 9, announced the appointment of a general advisory council for the department of health, and named eight committees, composed of prominent men and women of the city, to act as auxiliaries to the regularly employed officials of the department.

New Officers.—Physicians' Motor Club of Philadelphia: president, Dr. S. Leon Gans; vice presidents, Drs. John J. Robrecht, Charles R. Haig, Jr., and J. Torrance Rugh; secretary, Dr. Howard A. Sutton, and treasurer, Dr. Lewis H. Adler, Jr. Philadelphia Association of Industrial Medicine: president, Dr. Mervyn Ross Taylor; vice president, Dr. Lorne E. Hastings; secretary, Harry M. Gay, Camden, N. J., and treasurer, Dr. Robert Perry Cummins. West Philadelphia Medical Association: president, Dr. Henry B. Kobler; vice president, Dr. D. Clinton Guthrie; secretary, Dr. Henry G. Munson, and treasurer, Dr. Edmund L. Graf. Northern Medical Association: president, Dr. Mulford K. Fisher; vice president, Dr. James H. McKee; secretary, Dr. Robert Boyer, and treasurer, Dr. John W. Millick. West Branch Medical Society: chairman, Dr. Collin Foulkrod; vice chairman, Dr. D. Randall MacCarroll, and clerk, Dr. Ralph Getelman.

SOUTH CAROLINA

Work Against Trachoma.—Dr. Joseph L. Goodwyn, United States Public Health Service, has commenced his work in Lexington, and has already operated on and treated about fifty patients with trachoma.

Medical Society Meeting.—The annual meeting of the Charleston County Medical Society was held in Charleston, December 8, and the following officers were elected: president, Dr. Robert Wilson, Jr.; secretary, Dr. George F. Heidt, and treasurer, Joseph H. Cannon, all of Charleston.

Faculty Changes.—Dr. John Van de Erve, Milwaukee, has been elected professor of physiology in the Medical College of the State of South Carolina. Dr. Lane Mullally, who resigned as professor of obstetrics on account of ill health, has been elected emeritus professor of obstetrics and has been succeeded by Dr. G. Fraser Wilson. Dr. John F. Townsend, Charleston, has been elected assistant professor of ophthalmology and otology. Dr. Julius C. Sosnowski, Edward H. Sparkman, Jr., and Joseph S. Rhame, Jr., have been elected assistant professors of surgery.

VIRGINIA

Preventable Disease Commission Named.—Governor Davis has announced the appointment of Drs. N. Thomas Ennett and A. Murat Willis, Richmond; J. Hoge Ricks, Richmond; Lindsay Gordan, Louisa, and A. F. Thomas, Lynchburg, as members of the division of preventable disease authorized by the last session of the general assembly.

Hospital Items.—Buxton Hospital is building a new nurses' home, which it hopes to have completed by about

April 1, 1920.—A budget of \$350,000 has been submitted to the governor by the Hospital College of Medicine of Virginia. This includes the funds necessary to complete and equip the new negro hospital and the Dooley Hospital for contagious diseases and to maintain the three hospitals for one year.—Plans have been filed for an addition to the Stuart Circle Hospital, Richmond, to cost \$132,000. The new addition will be six stories in height and of fireproof construction.

Personal.—Dr. W. F. Rudd of the department of chemistry of the Medical College of Virginia, Richmond, has been elected president of the American Conference of Pharmaceutical Faculties.—Dr. Herbert Mann, Richmond, has been elected surgeon of the Virginia Penitentiary for a third term of four years.—Dr. John H. Crum, Louisa, has been placed in charge of the local station of the United States Public Health Service.—Dr. Howard Armstrong, Edom, has been elected city health officer of Harrisonburg.—Dr. Elisha L. McGill, Petersburg, has been appointed coroner of Dinwiddie County, succeeding Dr. William H. Crockford, Jr., deceased.

New Officers.—Lynchburg and Campbell County Medical Society, at its annual meeting in Lynchburg, December 21, elected Dr. John W. Carroll, president; Dr. Bernard H. Kyle, vice president, and Dr. Edward F. Younger, secretary-treasurer.—At the annual meeting of the medical faculty of Petersburg, the following officers were elected: president, Dr. Edwin J. Nixon; vice presidents, Drs. Fletcher J. Wright, Petersburg, and George Reese; secretary-treasurer, Dr. John M. Harwood, Richmond, and corresponding secretary, Dr. William C. Powell, Petersburg.—Prince George County Medical Association, at its annual meeting held in Hopewell, elected Dr. William D. Daniel, Disputanta, president.—At the annual meeting of the Richmond Academy of Medicine and Surgery, the following officers were elected: president, Dr. J. Garnett Nelson; vice presidents, Drs. Ramon D. Garcin, George C. Woodson, and William B. Porter; secretary, Dr. Mark W. Peyser (reelected); assistant secretary, Dr. Emmett H. Terrell (reelected), and Dr. Howard Urbach, treasurer (reelected), all of Richmond.

CANADA

New Montreal Hospital.—A bill has been introduced into the Quebec legislature for the incorporation of the St. Mary's Memorial Hospital in Montreal. The institution is intended to make up for the shortage of hospital accommodation in that city.

Public Health Statistics.—There were almost 2,000 fewer deaths from communicable diseases in Ontario in 1919 than in 1918. The great falling off is due to the absence of the influenza and pneumonia scourge which swept the province in the latter part of 1918. There were more tuberculosis fatalities in 1919, the total number being 1,722 as against 1,359 in 1918.

Public Health at Ottawa.—The public health department of the Canadian Conservation Commission at Ottawa has been placed under the new federal department of health. Dr. Charles A. Hodgetts, Ottawa, who has been for many years medical adviser to the conservation commission, takes office in the new department and is given charge of statistics, information, publication, library and circulation.

Smallpox.—The total number of smallpox cases in Toronto at the present time, January 8, is 449, eighteen new cases occurring a day. The epidemic seems to be declining. Altogether there have been about 2,000 cases.—The Provincial Board of Health of Ontario will take no further action toward compulsory vaccination in Toronto. The board recently applied to the court of appeal to compel the city to order general compulsory vaccination, but the order was refused by the judges, who stated the Ontario Vaccination Act had not been properly drawn.—Certificates of vaccination are no longer satisfactory to United States border authorities for Canadians entering that country. It must be shown that the operation has been successful.—The entire province of Quebec is now in a state of quarantine against Ontario. Even residents of Quebec who visit in Ontario will not be allowed to reenter their own province unless provided with a vaccination certificate.

GENERAL

Proctologists to Meet.—The American Proctological Society will hold its annual meeting in Memphis, Tenn., April 22 and 23, under the presidency of Dr. Collier F. Martin, Philadelphia.

Bill for Marine Hospital in California.—Julius Kahn of California has introduced a bill appropriating \$600,000 for the erection of a marine hospital on the present marine hospital site at San Francisco and to remove the present structure.

Child Labor Day.—The National Child Labor Committee announces that child labor day will be observed by churches on January 25, by synagogues, January 24, and by schools and clubs, January 26. On these days, the needs of children are to be discussed, viewing the subject in the higher moral aspects and urging the furtherance of child welfare activities.

Medical Men Needed for Overseas Service.—Brig.-Gen. Robert E. Noble, M. C., U. S. Army, makes an appeal for fifty medical men for Red Cross service overseas, for a period of at least one year. Practitioners are desired who have had military experience. The salary will be that of their previous rank in the military service with the 10 per cent. addition for overseas service and a liberal commutation allowance.

Joint Resolution for Control of Malaria.—Senator Harris of Georgia has introduced a joint resolution "to enable the Public Health Service to cooperate with states in the investigation and control of malaria." It provides for carrying on measures for the control of malaria through the respective state boards of health and the Federal Public Health Service. Five hundred thousand dollars were appropriated for the work, but no expenditures are to be made in any state until an equal sum shall have been appropriated by the legislature of a state or county or by individual contribution for malaria control work.

Committee on Industrial Dermatoses.—The National Safety Council, 168 North Michigan Avenue, Chicago, through a special committee is undertaking a survey of the relation of occupational factors to the production of skin diseases. The committee has issued a questionnaire designed to elicit information regarding the prevalence and distribution of industrial dermatoses, including any abnormalities of the skin or appendages that result from special manufacturing processes. The council proposes to compile the data, and to act as a clearing house for information on methods of control and treatment of industrial skin diseases.

Specialists Convene.—The Federation of Societies for Experimental Biology held its annual meeting in Cincinnati, December 29 to 31. This meeting would have been held in Toronto but for the smallpox quarantine. This federation includes the American Physiological Society, the American Bio-Chemical Society, the American Society of Pharmacologists, and the Society for Experimental Pathology. At the closing session of the American Bio-Chemical Society, Dr. Stanley J. Benedict, Ithaca, N. Y., was elected president; Dr. Victor C. Meyers, secretary, and Howard Bradley of the University of Wisconsin, Madison, treasurer.—Dr. William H. Park, New York City, was elected president of the Society for Experimental Pathology; Dr. Warren P. Lombard of the University of Michigan, Ann Arbor, president of the American Physiological Society, and Dr. Arthur S. Loevenhart, Madison, retiring president of the federation, president of the American Pharmacologists' Society.

Different Types of Botulism.—The department of animal husbandry of the University of Illinois for some years has been particularly interested in the subject of botulism and has made a serum for combating the disease. Specimens of the olives that were responsible for the outbreak of botulism in Detroit were sent to the department, which has reached the conclusion that this outbreak was due to a different strain of *Bacillus botulinus* than that heretofore isolated from contaminated food of animal or man. We have received the following statement on the subject from the university:

The Animal Husbandry Department of the University of Illinois, in studying a disease of animals commonly called forage poison, has apparently brought out the close relation of this disease to botulism in man. Experimental serum developed for the prevention of the disease in horses and mules has, in addition to veterinary use, been furnished on request to physicians for emergency treatment of botulism in man. In the light of our present knowledge, the immune serum, to be effective, must possess the highest degree of potency and should be used before symptoms appear or in the early stages of the disease.

A bacteriologic examination at the university of poisonous olives, recently implicated as the causative factor of the fatal food poisoning recognized as botulism in Detroit, has disclosed the fact that the strain of *Bacillus botulinus* encountered in the olives is a different and probably distinct type than heretofore isolated from contaminated food of animal or man, in our experience. This information is highly important to the veterinary and medical profession, in view of the more frequent recognition of this disease in recent years. In preliminary studies of botulism in animals, more frequently designated as forage

poisoning, all outbreaks studied to date occurring in the Mississippi Valley proved to be associated with a common strain of *B. botulinus*, but in view of tests recently conducted, it appears that more than one type of this disease may prevail.

It is obvious that if more than one type of poisonous micro-organisms of the botulinous type produce distinct and separate varieties of poisoning, botulinus antitoxin need be prepared against each disease producing strain if a consistent and high degree of efficiency is to be attained in prophylactic treatment. It is also reasonable to presume that the favorable results recorded in the laboratory may be gradually applied to natural outbreaks of this disease in animals with a fair degree of success and bid fair to curtail the tragedy of botulism in man.

FOREIGN

Prize Awarded to Escomel.—Among the prizes distributed by the Paris Académie de Médecine at its recent annual public meeting was one to Dr. E. Escomel of Arequipa, Peru. The Monbienne prize of 1,500 francs was divided between him and H. Velu of Casablanca.

Physicians as Aldermen.—The *Journal de médecine* of Bordeaux relates that the recent local elections resulted in four physicians being elected to the *Conseil municipal*, Professors Arnozan and Sigalas, the latter the dean of the university; Moure, the ear and throat specialist, and Lamarque.

Deaths in the Profession Abroad.—Dr. D. Boccardo, instructor in pathology at the University of Genoa, serving at the front during the war as radiologist, aged 44.—Dr. R. Rainaldi of Narni, Italy, author of works on neuro-pathology and forensic medicine, aged 63.—Dr. A. Werner, professor of chemistry at the University of Zurich, recipient of the Nobel prize in chemistry in 1913.

The Crisis in the Medical Journals.—Under this heading the *Policlinico* of Rome, the leading medical journal of Italy, comments on the lack of appreciation of the scientific press on the part of the authorities. They make no efforts to smooth the rocky path for the medical journals. In France, conditions are the same; a recent editorial in one was entitled "L'agonie des journaux scientifiques." The *Policlinico* states, "The daily press in Italy is allowed to buy paper at reduced rates and various other concessions are accorded the lay press, while the medical journals—which aided so materially in the winning of the war and in the maintaining of the public health at all times by the prompt dissemination of every progress in treating the sick and wounded and in preventive medicine—the medical press is allowed to be crushed by the high prices of paper and labor." The *Policlinico* compares with this disregard of the scientific press the opposite system in Germany, the privileges granted the leading medical journals in Germany. "During the war and since the war they have been able to get their paper much as usual and at reduced rates and their subsidies from the state have not been allowed to lapse. . . . And we victorious Latins are showing ourselves more barbarian than the barbarians!" The few "Zeitschriften" and "Archivs" that have reached America, published in 1918 and 1919, have the same paper, the same typographical appearance and the same size as the numbers issued before the war. The weeklies also compare favorably with the before-the-war issues except that the paper is of a slightly poorer grade.

LATIN AMERICA

Personal.—Dr. M. J. Wunderlich, Guatemala City, is now visiting in this country with his family.

Prophylactic Institute in Paraguay.—Under the direction of Dr. Victor Idoyaga a prophylactic institute has been organized recently in La Asunción.

Pasteur Institute in Nicaragua.—Recently a Pasteur Institute has been inaugurated at Managua, Nicaragua, presented to that country by the president of Mexico. The institute has therefore been named Instituto Antirábico Carranza.

New Sanitary Regulations in Santo Domingo.—A recent amendment to the sanitary code of Santo Domingo divides all towns for sanitary purposes into four groups according to their population; namely, of less than 1,000 inhabitants; from 1,000 to 5,000; from 5,000 to 10,000, and over 10,000.

Public Health Association in Colombia.—There has been organized at Bogotá an association under the name Sociedad Sanitaria de Bogotá, which will have for its purpose the cleaning of the city in order to eradicate all infectious diseases having for their cause impure water supplies and personal uncleanness.

Congress of Practitioners.—The Sociedade de Medicina e Cirurgia of Rio de Janeiro has taken the initiative in organizing a Congresso dos Medicos Praticos to be held in con-

nection with the Pan-American Medical Congress on the occasion of the celebration of the centenary of the independence of Brazil. The Practitioners' Congress will have five sections: public hospitals and other charities; public health and preventive medicine; social medicine; practice of the profession, and medical education. The *Brazil-Medico* gives the five to ten different topics appointed for discussion in these five sections. Among the topics to be discussed in the section on medical education are the limitation of the number of medical students; national graduate courses, and study trips to other lands. This section is in charge of Prof. Miguel Couto.

Personnel of the Medical Corps

For the week ending January 9, the Medical Corps contained 2,153 medical officers; the Medical Reserve Corps contained 4,348 officers, an increase of 99 over the previous week.

Legislation in Interest of Reserve Officers

A bill has been introduced by Congressman S. R. Sells of Tennessee which provides that allowances of officers in the Medical Reserve Corps of the Army shall be computed in accordance with the time served by them as contract surgeons. This bill would give longevity pay allowances as contract surgeons in addition to the time they are in the regular service.

New Legislation for Army Medical Corps

January 9, Senator Wadsworth of New York, chairman of the Committee on Military Affairs, introduced the Army reorganization bill in the Senate. Section 33 of this bill relates to the medical service of the Army, and will create a large number of vacancies in the Medical Corps in the grades of major, lieutenant-colonel and colonel. This is due to the fact that the bill fixes certain age limits in promoting medical officers now in the Army, and few present officers can qualify. For instance, this section provides that "commissioned officers shall be promoted to the grade of captain on completion of three years' service; major fourteen years, lieutenant-colonel, twenty and colonel twenty-six years' service." Vacancies thus created will be filled by appointment, on due examination, from "persons under the age of 50 years who shall have served as officers in the Medical, Dental or Veterinary Corps in the U. S. Army between April 6, 1917 and Nov. 11, 1918." The Wadsworth bill also contains a provision for commissioning the Army Nurse Corps. The bill substantially adopts the so-called Riker-Jones bill, which has been before Congress for several months, and will make Army nurses commissioned officers. Nurses who act as superintendents will have the relative rank of major; assistant superintendents, directors and assistant directors, the relative rank of captain; chief nurses, the relative rank of first lieutenant, and nurses the relative rank of second lieutenant. Nurses will wear insignia to indicate their rank as may be prescribed by Army regulations. The Wadsworth bill will become the committee bill because Senator Wadsworth is chairman of the Committee on Military Affairs, and it is quite likely that this bill will be the basis of all military legislation at the present Congress. The bill contains provision for a system of universal military training for youths between 18 and 21, the recognition of the National Guard of the United States in each state and the maintenance of the Reserve Officers' Training Corps.

Foreign Correspondence

LONDON

Dec. 17, 1919.

The Number of New Practitioners Registered

At the General Medical Council, the president, Sir Donald Macalister, delivered an address in which he stated that two years ago he predicted that in 1919 the number of new physicians registered would be far below the average. The registrations to date proved the truth of his prophecy, although some compensation had been afforded by the addition of 400 British practitioners to the colonial list of the register. The province of Alberta in Canada had now legislated in favor of medical reciprocity with the United Kingdom. Only one province of the Dominions, British Columbia, now remained outside the agreements concluded between the United Kingdom and the British Empire beyond the seas. The number of registered medical and dental students for 1919 are, as was also foreseen, greatly in excess of former records. They are filling the schools to overflowing. Some schools, indeed, have had to postpone all fresh admissions until next April. Apparently in a few years the professional ranks will be more than replenished. In some minds the expected influx is causing anxiety lest the new practitioners may not all find employment when they reach the register. But the wastage of war has been great and the openings for skilled men and women would be multiplied by the increased activities of the new authorities concerned with the conservation of the health and physical welfare of the people. There would, in fact, be many new demands which no doubt would ultimately match the new supplies.

Representatives of the National Board of Medical Examiners of the United States recently visited this country with the object of studying and reporting on the methods employed here for the testing of candidates for medical qualification and for the control of their registration as practitioners. The registrar was instructed to place at their disposal the fullest information which the office possessed. By courtesy of the licensing bodies the representatives attended a number of the qualifying examinations. They stated that they derived much valuable knowledge from their visit. The influential movement toward the establishment of a high and uniform standard of professional qualification throughout the American commonwealth, of which the National Board of Medical Examiners is the expression, might have issues of importance extending beyond the United States.

Tribal Ties in Modern Nations

Prof. Arthur Keith delivered the Boyle lecture before the Junior Scientific Club at Oxford on this subject and threw a philosophical light on problems that have proved very thorny for the politicians. He said that the modern problems of race and nationality were due to the struggle between inherited tribal instincts and the conditions of existing civilization. We had broken up or were attempting to break up Nature's ancient tribal machinery, and were striving to replace her designs by others evolved in the minds of modern statesmen and politicians. The United States showed one of the most acute of the struggles that arise whenever races or nationalities came into close contact. Within the frontiers of the States was massed a population of 110 millions. More than 10 millions of these were marked off from the rest by a frontier, a color line, as sharply defined and jealously guarded as the frontiers of a kingdom. Across that racial frontier all legitimate social traffic was barred, the custodians of the frontier line being those who stood on the white side. Any attempt to cross produced mob war. While these 10 millions of segregated citizens abode within their racial fence they saw millions arise from Europe and pass freely through the national and social gateways which for them were barred. In the course of a generation they saw these new arrivals become slowly stripped of their alien outlook and gradually incorporated within a new national mass. In the States, then, a machinery was at work which maintained racial frontiers but broke down all national barriers. In Canada a mechanism was at work which converted immigrants of alien nationalities into loyal Canadians. But the artificial segregation of French Canadians in the province of Quebec might tend to turn a national differentiation into a racial differentiation. On the other hand, on the Pacific Coast there was a tendency to maintain a racial barrier against the Japanese and Chinese. In Spanish America a huge problem had arisen because,

while the Nordic race in North America had maintained its distinctness from Indian blood, in Mexico and South America an Iberian stock of European origin had blended with Indian blood. The Nordic European had preserved a feeling of race caste absent in the Iberian European, more closely akin to African races. A still more potent historical influence was that the Iberian immigrants had originally been male adventurers in whom the sex instinct overcame race instinct, whereas the Nordic immigrants had been of both sexes.

There were two processes of nationalization at work in Europe. All the great nationalities of Europe—France, Germany, Great Britain, Italy and Spain—had been built up by fusion. In these cases the process had been from above downward, from statesmen and rulers to the people. On the other hand, Nature's method was by disruption. The people of Norway and Sweden were of the same racial composition, and union would have given them strength. But a tribal feeling which swept through the people of Norway compelled a disruption. Ireland was another case in which the tribal instinct had flamed up, producing a desire for separation, which had no basis in race or interests. Force would be no response. All that a statesman could do was to provide conditions in which a favorable spirit was most likely to develop and mature.

Belgian Surgical Congress

THE WILLEMS METHOD

It was appropriate that after five years of war the first meeting of the Belgian Surgical Society, observing the twenty-fifth anniversary of its foundation, should celebrate the most valuable acquisition that the surgery of the war has given us, namely, immediate active mobilization in joint lesions. The treatment that Willems introduced has brought fame to Belgian surgery, and at the present time the Willems method is accepted in principle by all surgeons of the Allies. At the meeting held September 27, Willems described the excellent results secured by his therapeutic method. The indications for this treatment have been extended, and it would seem now that the principle of immediate active mobilization should be applied in all joint lesions, whether simple or compound, and even in the septic complications of purulent arthritis. No doubt there are cases in which the method cannot be applied inflexibly, for instance, in extensive bone fractures, or in lesions of the extensor muscles that forcibly limit the use of voluntary mobilization on the part of the patient himself. However, even in such cases a slight attempt at voluntary movements, supplemented by passive mobilization, will render good service. At this meeting of the Belgian Surgical Society, Willems emphasized especially certain details in the application of the method and the necessity of prolonging the mobilizing treatment over a long period of time. Willems stated that very often the failures reported by certain writers after using his method are due to its incorrect application. Above all, mobilization must be immediate and active. These two conditions must be strictly carried out, and their observance requires a well trained hospital personnel. If proper precautions are taken, it would not seem that treatment by means of mobilization is contra-indicated in any joint lesion; for, even in extensive bone fractures, mobilization in the splint can be begun while at the same time the fracture is being reduced.

A distinction must be made between the elbow and the knee: In the case of the elbow, conservation of mobility; in the knee, of solidity, is the principal thing. In certain cases in which the knee has been kept mobile, it will occasionally be necessary to have recourse to an extra support in order to consolidate a joint that is badly shattered. Willems rejects all primary resections for the reason that they appear to him to rest on a premature decision; to his mind secondary resections are alone indicated.

While paying homage to M. Willems as the inventor of this method during the war, Delrez reported the results that he had secured by the use of the method; he also endeavored to point out the limits of its application. He is more conservative than the author of the method and as a rule refrains from applying it in case the joint wound is complicated by extensive damage to muscles, chiefly through fear of setting up an infection. Aside from this restriction, the treatment recommended by Delrez is identical with that of Willems. We shall not take up again the operative technic that is applicable in joint wounds or the indications for intervention, as these questions have already been discussed; but

let us note especially in Delrez' report the restorative operations that he had occasion to perform on the war wounded. In wounds of the shoulder in case the deltoid has been severed transversely, causing a linear scar which prevents the elevation of the arm, relief may be secured secondarily by excision of the cicatricial tissue and suturing of the two muscle fragments. The member is kept in abduction for a certain length of time. Delrez referred to several cases of loose shoulder and elbow joints that were treated by suspension, the results of which were very encouraging; also to transplant operations in the region of the knee; once of a condyle, another time of a patella, taken from the cadaver and preserved in alcohol.

SURGICAL TREATMENT IN POTT'S DISEASE

The second topic treated at the surgical congress is likewise of great importance. A lengthy discussion arose in regard to the therapeutic treatment of Pott's disease. The American authors recommend immobilization of the vertebral joints in the vicinity of the lesion either by arthrodesis of the arches of the vertebrae and transposition of the spinous processes (Hibbs) or by grafting pieces of bone into the spinous processes (Albee). The French authors (Calvé especially) are opposed to such intervention ordinarily and apply it only in cases of recovery from Pott's disease in order to give greater solidity and make the cure more definite. Calot is of the same opinion; in fact, he goes so far as to claim to be the originator of the Hibbs method, although he combats it.

Maffei has, since 1914, given treatment in fifty-three cases of Pott's disease, in nineteen of which the Albee method of operation was employed. He called special attention to the fact that in 1915 and 1916 the patients operated on recovered much more slowly and with greater difficulty, which he thinks was due to undernutrition consequent on the bad food conditions during the occupation. In seventeen cases a prompt cure was effected. He considers that the Albee operation is conservative, capable of immobilizing the lesions and therefore justified. However, its curative value in Pott's disease is negligible; the evolution of the disease continues.

Lorthioir, who also gave a report, agreed with Maffei that the operation of itself did not effect a cure. It is, he stated, a simple means of fixation which avoids the necessity of immobilizing the patient or of the wearing of a plaster cast or a corrective brace. This was the only consideration (a palliative and not a curative operation) that guided him in the cases in which he operated by the Albee method and used a tibial or a costal graft. General statistics on the subject that he has gathered in regard to operative methods and to conservative methods lead him to the rather significant conclusion that the percentage of mortality in cases in which general operative methods were employed was 7.6, and in cases in which conservative methods were used, 7.7. From these facts, Lorthioir added, the conclusion may be reached that the operative method has only minimal influence on the mortality rate in Pott's disease, but that it does exert an influence on the duration of treatment, shortening it to an extent worth while, and also saving the patient the long torture of forced immobilization, either total or partial.

THORACOPULMONARY WOUNDS

The studies of thoracic wounds carried out by Derache and by Janssen give a summary of the statistics of the war on the Belgian front. The anatomic study of wounds, the symptomatology, and the complications of pleuropulmonary traumas constitute the principal chapters of these two interesting reports. They take up especially the septic complications of hemothorax and the treatment of pyothorax. The short drain and irreversible drainage by Delagenière's valve drain are the two best means of draining a pyothorax. Pleural lavage is not often indicated. However, Depage and Tuffier secured remarkable results by sterilization of the pleural cavity by means of interrupted irrigations of surgical solution of chlorinated soda (Dakin's solution), which allows of early closure of the thorax.

The two essayists spoke highly of Pierre Duval, the great originator of war surgery of the lung. The clearer conceptions in regard to the relatively slight gravity of operative pneumothorax opened up at once renewed activity in the whole domain of intrathoracic surgery. The extraction of intrapulmonary projectiles by means of a wide opening in the thorax has caused a revolution in pulmonary surgery that is very hopeful. The technic of this intervention has now been definitely determined. It remains to fix the operative indications. Janssen says in his report that many authors recommend systematic intervention and that he feels more and more inclined to coincide with their views. Derache is

less decided; he thinks that many times shell fragments and bullets may be well tolerated. He believes that definite indications for this intervention should be present and that no absolute formula should be set up. The decision may well be left to the surgeon's clinical judgment. Furthermore, certain objective signs will furnish elements that will aid in reaching a decision, for example, repeated slight hemoptysis, sharp pains accompanied by dyspnea, pulmonary congestion, and formation of an abscess.

PARIS

Dec. 11, 1919.

Hospital Ships During the War

Dr. Chevalier, general medical inspector of the Public Health and Marine Hospital Service, recently made an interesting report to the Academy of Medicine on the subject of hospital ships during the war. The part that these ships were to play during the war proved to be quite different from what was anticipated. As there were no great naval combats, they helped transport to the interior the wounded coming from the various battle areas. During the first month of the war they aided in transporting the wounded of the army of Flanders, thus supplementing the inadequate transportation facilities of the railroads. At the beginning of February, 1915, they began to operate in the Mediterranean, bringing home 220,000 wounded and sick from various Mediterranean fronts in the East. Toulon and Bizerta received 147,000 and 64,000, respectively, while in the ports of Algeria 5,000 were debarked. After the first conflicts in the Dardanelles a certain proportion of the sick and wounded were taken to Egypt. The ports of debarkation were informed in advance by wireless of the number of wounded on board the ships. Experience has shown that the hospital ships constitute a most valuable means of evacuating the sick and the wounded. The men are well quartered, well fed and have constant medical care. The rocking of the boat is the only disadvantage, but this is very slight owing to the great size of the steamers, and is at least preferable to the shaking of the railway trains. A great amount of surgical work was done on board. In one instance a single surgeon, during the course of several voyages representing thirty-nine days of hospitalization, treated 1,884 wounded and performed 155 major operations. Another surgeon, in fifteen crossings, performed 968 operations, 300 of which were under general anesthesia. It is to be hoped that in the future, instead of its being necessary in an emergency to use boats that have been remodeled, enough hospital ships will be constructed in advance, according to special plans, and that the medical supplies for these ships will also be on hand in ample quantities in whatever port constitutes their base.

Conference of French and Swiss University Authorities

At the invitation of the University of Geneva, a conference of French and Swiss university authorities was held recently. Delegates from the French universities and from the Swiss universities, including both those of so-called French and of German Switzerland, convened at Geneva and took up the question of establishing proper university relations between the two countries, particularly as regards the exchange of students and professors. The medical faculties were represented at the conference by four Swiss professors and by two French professors, the regretted Lépine of Lyons and Dr. J. Vanverts, professor in the University of Lille. The conference passed a resolution to the effect that French and Swiss medical students holding a baccalaureate degree and provided with a certificate of maturity, whether French or Swiss, may be matriculated in the universities of either country and may receive full credit for work done.

Commemorative Tablet to French Physicians Killed in Battle

At a meeting held December 9, the Academy of Medicine decided to erect a stele in the Hall of Fame in commemoration of the members of the medical corps who died on the battlefield. The execution of the stele will be entrusted to Dr. Paul Richer, professor in the School of Fine Arts and member of the Academy of Medicine.

Departure of the Canadian Red Cross

The Canadian Red Cross, which is about to withdraw from France, gave recently a farewell reception at which a representative of the undersecretary of the army medical corps, as well as M. Justin Godart, the former undersecretary, were present. Without counting the Canadian Hospital, which

has 520 beds and cost 2,000,000 francs, the Canadian Red Cross has turned over 2,000,000 francs to the French Red Cross and to various other welfare societies. A gift of 1,300,000 francs was also made to the president of the French republic in aid of the refugees, so that the Canadian Red Cross has expended in France a total sum of 30,550,646 francs.

Reeducation of Disabled Alsatians and Lorrainers

A decision has been reached that enlisted men and officers residing in Alsace or Lorraine who are suffering from disabilities arising from wounds and diseases contracted or aggravated during the war may secure admission to a special school of reeducation with a view to their being trained and placed in some industry or profession, provided they are of French origin or come within the category of persons permitted by the treaty of peace with Germany to be reclaimed as French nationals, and provided further that those requesting admission to such schools shall have reclaimed French nationality before making their request. The Landesfürsorgestelle für Kriegsinvaliden, which was created, June 3, 1915, under the German administration, has been transformed into the Institut des mutilés, réformés et veuves de guerre d'Alsace et de Lorraine, the purpose of which is to serve as a clearing house for information concerning the action of various administrative and private societies; to encourage and facilitate the reeducation of the disabled; to study into the regulations and legislative enactments that may be of advantage to certain persons interested, and, in a general way, to secure for such persons the help and support that they may need and are their due.

The Closing of a School of Reeducation

The School of Reeducation of Maison-Blanche, located in Neuilly-sur-Marne, department of the Seine-et-Oise, founded in July, 1916, by the Union des colonies étrangères en France en faveur des victimes de la guerre, has just closed its doors after more than three years of labor devoted to the reeducation of war cripples. During this period, this school reeducated more than 3,000 partially disabled men, preparing them for twenty or more different trades or professions. Positions were secured for a large number of these immediately on leaving the school. The funds for the support of this school, amounting to more than a million francs, were furnished entirely by a generous citizen of the United States, Edward T. Stotesbury of Philadelphia.

MEXICO CITY

Jan. 4, 1920.

Yellow Fever

Yellow fever is apparently spreading in this country, since a case has been reported at the port of Salina Cruz on the Pacific Coast far from Yucatan, the focus of the present epidemic. Dr. Noguchi has already begun his efforts to eradicate the disease, employing for this purpose his method of prophylactic vaccination by means of killed cultures of *Leptospira*. It is expected that this vaccine will give good results in view of the fact that yellow fever is one of those diseases that confer complete and permanent immunity and that the germ isolated by Dr. Noguchi is apparently the etiologic agent of this disease.

It is stated here that the sanitary authorities of Washington, having in mind the possibility of this disease spreading to the United States, have designated a commission composed of sanitarians and bacteriologists to come to this country and study the subject.

Noguchi has also presented to the Instituto Bacteriológico Nacional a dozen monkeys which will be utilized to carry out experiments on typhus fever (these animals being sensitive to the virus of this disease) and also to try the curative value which is claimed for a dog serum prepared here by inoculating dogs with the blood from typhus fever patients.

Death Due to Arsphenamin

A few days ago there happened in this town a death in a physician's office, caused by an injection with arsphenamin. The patient, about 24 years of age, was in the secondary stage of the disease with no apparent visceral lesions, and had a good physique. The injection was the third one, and German salvarsan was employed in doses of 30 cg. dissolved in 15 c.c. of distilled water without previous alkalization and being administered with a syringe. Respiratory symptoms occurred almost immediately, and the patient succumbed to acute dyspnea in about five minutes. Necropsy revealed a unilateral suppurating pyelitis and many enlarged blood ves-

sels in both lungs, accompanied by embolisms of the same vessels. The two previous injections were administered at intervals of a week, in the same amount as the fatal one and with the same technic. In this case the death must be attributed to the defective technic and not to the drug, since it was obviously at fault in two respects, the acidity of the solution and the very small amount of the vehicle, which should have been at least 75 c.c. If no accident happened during the first injections, it may perhaps be attributed to the existence at the time of sufficient alkali reserve for the neutralization and redissolution of the arsphenamin.

Campaign Against Syphilis

The municipal council of the city of Puebla has adopted the proposal of Dr. Camarillo, who advocates that the municipal councils of the whole country should unite to formulate a program for a campaign against syphilis, to arrest contagion at its source. His plan is to treat energetically the contagious sores of prostitutes in the hospitals, so that these creatures may receive the benefit of modern arsenical medication. In Dr. Camarillo's opinion, it is criminal to isolate prostitutes and treat them only with mercury, since their lesions reappear afterward. He wants to have street-walkers properly cared for and forbid them to practice their profession, unless in addition to the lack of contagious lesions they give negative Wassermann reactions. For this purpose they will be compelled to have a sanitary card in which will be noted their sanitary condition from clinical and serologic standpoints.

Personal

During the year 1920 the position of mayor of the City of Mexico will be filled by Dr. Luis Coyula, former professor of physiology of the School of Medicine and a prominent journalist.

BUENOS AIRES

Nov. 25, 1919.

Anesthesia

The Association of Surgery has devoted several meetings to discussions on general anesthesia, the consensus being in favor of ether.

Thyroid Disorders

The Medical Society has devoted its special meetings this year to a study of hyperthyroidism and exophthalmic goiter. Drs. Lozano and Kraus discussed the first subject and Drs. Hardoy, Houssay, Escudero, Peralta Ramos and Domínguez the second.

Lecture on War Surgery

Dr. Pedro Chutro, who has just arrived from the United States, has given a series of lectures on war surgery in the School of Medicine.

Surgical Aeroplanes

Dr. Beretervide has declared that he intends to organize a service of aeroplanes to carry all the equipment necessary for surgical operations. In this way there can be performed any emergency operations that may be required in out of the way places.

Professorial Appointments

Dr. Pedro Chutro has been appointed professor of clinical surgery and Dr. B. A. Houssay professor of physiology in the School of Medicine of Buenos Aires. There has been approved the foundation of an institute of physiology which will include chairs of physiology, chemistry and biologic chemistry.

Marriages

ALBERT LEROY BROWN, Captain, M. C., U. S. Army, Douglas, Ariz.; to Miss Vlasta Coffey of Ellsworth, Kan., at Douglas, November 12.

FRED LOWE SOPER, Sao Paulo, Brazil, formerly of Chicago, to Miss Juliet Snider of Fort Scott, Kan., December 27.

ALFRED LEE LOOMIS BELL, Englewood, N. J., to Miss Grace Pauline Seidel of Philadelphia, January 1.

WILLIS CLARENCE KOOLS, Holland, Mich., to Miss Wilma Denabel, at Kalamazoo, in November.

CHAPIN CARPENTER, Wayne, Pa., to Miss Mary Ruth Smyth, at Pottsville, Pa., December 27.

ROBERT SHAFER, to Miss Ruth Hollis Taneyhill, both of Baltimore, December 27.

Deaths

Christian Rasmus Holmes, dean of the Medical Department of the University of Cincinnati, died in the Post-Graduate Hospital, New York City, January 9.

Dr. Holmes was born in Denmark, Oct. 18, 1857. His early education in Denmark and Germany was in civil engineering. On the death of his father he came with his mother to Cincinnati, beginning the study of medicine in the Miami Medical College, graduating in 1886. He became assistant to Dr. Joseph Aub, well known ophthalmologist of Cincinnati, and succeeded him in this specialty.

In 1892, Dr. Holmes became a member of the City Hospital staff. He appreciated the necessity of a city hospital worthy the name, and of the consolidation of the warring factions of the two chief medical colleges in the city. In the attainment of the first object, the establishment of an adequate general hospital in Cincinnati, he spent ten years of arduous labor in the hospitals of the United States and Europe. The result of these labors stands today as Dr. Holmes' greatest monument, the Cincinnati General Hospital. Dr. Holmes aided greatly in the consummation of the merger of the Medical College of Ohio and the Miami Medical College into the University of Cincinnati in 1909. The two colleges were made an integral part of the University of Cincinnati, with Dr. Holmes as dean of the new institution. In order to secure the union of the two colleges, Dr. Holmes helped in framing the charter which made the medical department of the hospital a part of the university whose trustees should have the sole right to elect the staff and supervise the nursing department.

Dr. Holmes was commissioned major, M. R. C., 1917, and placed in charge of the eye, ear, nose and throat department at the base hospital, Camp Sherman, Chillicothe, Ohio, where he remained until the end of hostilities.

Dr. Holmes was a prolific contributor to the literature regarding hospitals and their relation to medical education and to the literature of his specialty. He served as professor of otology in Miami Medical College from 1890 to 1904, as professor of ophthalmology in the Laura Memorial Medical College and Presbyterian Hospital from 1892 to 1903, and as professor of otology and dean of the University of Cincinnati since 1904. He was ophthalmologist and otologist to the Cincinnati Hospital from 1888 to 1899, and has been consulting ophthalmologist to the institution since 1908. He was third vice president of the American Medical Association in 1902-1903, chairman of the Section on Laryngology and Otology in 1904 and 1905, and of the Section on Ophthalmology in 1905-1906. He was president of the American Academy of Ophthalmology and Oto-Laryngology in 1901 and 1902, of the American Ophthalmological, Rhinological and Otological Society in 1908-1909, and of the Cincinnati Academy of Medicine.

Dr. Holmes was an idealist and enthusiast, and worked with untiring energy, sacrificing health and fortune to the accomplishment of the great plans which he had conceived.

Emery Marvel ♂ Atlantic City, N. J.; second vice president of the American Medical Association; died January 8, after a surgical operation. Dr. Marvel was born in Dover, Del., in 1868, and received his medical degree from the University of Pennsylvania, Philadelphia, in 1895; he was a member of the American Association of Obstetricians and Gynecologists, and of the New York Academy of Medicine. Dr. Marvel made a specialty of surgery and was surgeon to the Atlantic City Hospital, consulting surgeon to the Jewish Seashore Home, and had been physician to St. Michael's Children's Hospital, Atlantic City. Dr. Marvel in addition to being vice president of the Association has been a member of the House of Delegates; he was always an active worker at the many annual sessions of the Association held in Atlantic City. Last year he was chairman of the committee of arrangements; those who were present at the session will testify to the splendid executive ability he displayed at that meeting.

Charles McIntire ♂ Easton, Pa.; University of Pennsylvania, Philadelphia, 1883; aged 72; secretary of Northampton County Medical Society from 1878 to 1897 and president in 1900; president of the Lehigh Valley Medical Association in 1907; secretary of the American Academy of Medicine from 1891 to 1902, and from 1903 to 1915, president in 1902 and 1903, and treasurer since 1915; a specialist in ophthalmology;

assistant in chemistry from 1868 to 1870, adjunct professor of chemistry from 1870 to 1874, and lecturer on sanitary science from 1880 to 1905, in Lafayette (Pa.) College; editor of the *Lehigh Valley Medical Association Journal* for several years, and of the *Bulletin of the American Academy of Medicine*, since 1896; died January 4.

Lorenzo P. Gibson ♂ Little Rock, Ark.; Jefferson Medical College, 1877; aged 62; demonstrator of anatomy in the University of Arkansas from 1878 to 1903; acting assistant surgeon United States Marine Hospital Service since 1892; vice president of the American Medical Association, 1890-1891; president of the Arkansas Medical Society in 1895-1896; ex-president of the College of Physicians and Surgeons, Little Rock Medical Society and Pulaski County Medical Society; editor of the *Journal of the Arkansas Medical Society* for fifteen years; formerly secretary of the Arkansas State Board of Health; died December 29, from pneumonia.

Lucien F. Salomon, New Orleans: Tulane University, New Orleans, 1872; aged 69; a member of the Louisiana State Medical Association, a well known expert on yellow fever and typhoid fever; secretary of the Louisiana State Board of Health from 1886 to 1894; acting assistant surgeon U. S. Army in 1884 during the yellow fever epidemic; who investigated sanitary conditions in Jamaica in 1885 and in Porto Rico in 1898 for the United States government; for two terms president of the New Orleans Medical and Surgical Association; died December 31, from heart disease.

William Edward Grant, Louisville, Ky.; Jefferson Medical College, 1886; Kentucky School of Medicine, Louisville, 1887; aged 74; a member of the Kentucky State Medical Association; health officer of the city of Louisville from 1909 to 1917; professor of medical life insurance and dean of the University of Louisville, Medical Department, from 1911 to 1914, and at the time of his death registrar of vital statistics for Jefferson County; died from angina pectoris, January 3.

Andrew Nelson Lerskov, Claremore, Okla.; University of Nashville, Tenn., 1907; aged 35; a member of the Oklahoma State Medical Association; formerly secretary of the Rogers County Medical Society and superintendent of health of Rogers County; First Lieutenant, M. R. C., U. S. Army, and honorably discharged Dec. 7, 1918; died in Kansas City, Mo., in November, from tuberculous peritonitis.

Charles S. Harle, Clifton, Ariz.; University of Louisville, Ky., 1892; aged 49; a member of the Arizona Medical Association; who practiced for several years in Chihuahua, Mexico, and spent ten years in prison, following his conviction for complicity in the murder of several men for their life insurance, and was afterward surgeon-general of Villa's armies, died in Abilene, Texas, December 30.

Warwick Miller Cowgill ♂ Lincoln, Neb.; University of Louisville, Ky., 1883; aged 62; who limited his practice exclusively to diseases of the eye, ear, nose and throat; for many years ophthalmic and aural surgeon for the Louisville and Memphis divisions of the Illinois Central System, at Paducah, Ky.; died in St. Elizabeth's Hospital, Lincoln, December 29, from nephritis.

Neidhard Hahnemann Houghton ♂ Boston; New York Homeopathic Medical College, New York City, 1887; aged 58; associate professor of diseases of the nose and throat in the medical department of Boston University; died in the Massachusetts Homeopathic Hospital, Boston, December 26, from injuries received when struck by a streetcar in Brookline, a short time before.

John F. Glover, Evansville, Ind.; University of Illinois, Chicago, 1888; aged 64; a member of the Indiana State Medical Association; for many years assistant superintendent of the Southern Indiana Hospital for the Insane, Woodmere, Evansville, and secretary of the Evansville Board of Health; died December 28, in the Walker Hospital, Evansville, from heart disease.

William Harold Townsend ♂ Sac City, Iowa; State University of Iowa, Iowa City, 1897; aged 50; assistant surgeon of the Fifty-Second Iowa Infantry, U. S. V., during the war with Spain; once mayor of Sac City and for sixteen years coroner of Sac County; died December 24 from carcinoma.

Thomas Estill Holland ♂ Hot Springs, Ark.; Missouri Medical College, St. Louis, 1874; aged 70; formerly president of the Medical Association of the Southwest; formerly Lieut.-Col., M. C., Mo. N. G.; a member of the staff of the Ozark Sanitarium; died December 21.

John D. Cope, Negley, Ohio; American Eclectic Medical College, Cincinnati, 1882; aged 70; was thrown from his

buggy in a runaway accident near his home, December 22, sustaining a fracture of the skull and other injuries from which he died ten hours later.

Oliver Tracy Logan, Changteh, Hunan, China; Medical College of Indiana, Indianapolis, 1895; aged 49; for twenty-three years a medical missionary of the Presbyterian Board in China; died December 7 in China as the result of an accidental gunshot wound.

Willard Clyde Foster • Casper, Wyo.; University of Minnesota, Minneapolis, 1902; aged 42; formerly local surgeon of the Colorado Fuel and Iron Company and the Colorado Midland Railway at Gulch, Colo.; was killed in an automobile accident, recently.

Edward C. Ellerbrock, St. Louis; Homeopathic Medical College of Missouri, St. Louis, 1896; St. Louis College of Physicians and Surgeons, 1902; aged 64; died in the St. Louis City Hospital, December 25, from accidental poisoning by bichloride of mercury.

Benjamin Franklin Archer, Sweet Water, Texas; Tulane University, New Orleans, 1861; aged 85; surgeon of a Mississippi regiment in the Confederate service during the Civil War; representative in the state legislature from 1872 to 1874; died December 14.

Elva A. Cram, Great Falls, Mont.; Kentucky School of Medicine, Louisville, 1903; aged 42; a member of the Kentucky State Medical Association and for several years a practitioner of Peach Grove, Ky., died December 26, from pulmonary tuberculosis.

Mary Caroline Hollister, Chicago; Northwestern University Woman's Medical School, Chicago, 1882; aged 59; a member of the Illinois State Medical Society; a specialist on diseases of the eye and ear; died at her winter home, Lake Worth, Fla., January 2.

Walter Ralie Francis, Bowling Green, Ky.; Cincinnati College of Medicine and Surgery, 1881; aged 63; a member of the Kentucky State Medical Association; died in St. Joseph's Hospital, Bowling Green, December 24, from pneumonia.

Marcus H. White, Roseburg, Ore.; Keokuk, Iowa, Medical College, 1891; aged 76; a veteran of the Civil War; for twenty-five years a practitioner of Portland; died at the Oregon Soldiers' Home, Roseburg, October 23, from paralysis agitans.

Robert M. Foster • Russellville, Ind.; Kentucky School of Medicine, Louisville, 1903; aged 48; died in the L. L. Culver Union Hospital, Crawfordsville, Ind., December 29, from peritonitis two weeks after an operation for appendicitis.

Corydon S. McClain, Springfield, Mo.; College of Physicians and Surgeons, Keokuk, Iowa, 1870; aged 76; formerly one of the editors of the *Springfield Advertiser*; was found dead, December 22, from gas asphyxiation.

Benjamin Davis, New Carlisle, Ohio; Medical College of Indiana, Indianapolis, 1879; aged 73; president of the Clark County Health Board; died at the home of his daughter in Osborn, Ohio, December 23, from heart disease.

Peter C. Guinan, Rochester, N. Y.; University of Buffalo, N. Y., 1887; aged 64; a member of the Medical Society of the State of New York; died in the Rochester General Hospital, January 4, from cerebral hemorrhage.

James Pittman, Cincinnati, Ark.; St. Louis College of Physicians and Surgeons, 1898; aged 48; a member of the Arkansas Medical Society; died in the City Hospital, Fayetteville, Ark., December 18, from appendicitis.

Joseph William Little, Washington, D. C.; George Washington University, Washington, D. C., 1872; aged 76; a member of the Medical Society of the District of Columbia; died December 28, from myocarditis.

Cephas L. Carroll, Taylorville, Ill.; Detroit Medical College, 1870; aged 83; died in St. Vincent's Hospital, Taylorville, December 26, a few hours after an operation for the removal of stones of the bladder.

Rachael Swain, Indianapolis; Northwestern University Woman's Medical School, Chicago, 1882; aged 80; who had been spending the winter in Long Beach, Calif., died December 31.

Benjamin Griffiths Beddoe • Scranton, Pa.; Jefferson Medical College, 1890; aged 64; a member of the staff of the West Side Hospital, Scranton; died December 24, from pneumonia.

Harry J. Garber, Essexville, Mich.; Homeopathic Hospital College, Cleveland, 1889; aged 53; died in Grace Hospital, Detroit, December 17, from carcinoma of the esophagus.

William Rutherford Young • Long Beach, Calif.; State University of Iowa, 1893; aged 51; for many years a practitioner of Ansley, Neb.; died December 22, from heart disease.

Edmund Gerrish Dearborn, Antrim, N. H.; Harvard Medical School, 1904; aged 40; a member of the New Hampshire Medical Society; died in Nashua N. H., November 30.

Martin F. Moore • Ottumwa, Iowa; Keokuk, Iowa, Medical College, 1898; aged 44; died December 27, at the Ottumwa Hospital from heart disease, after a sinus operation.

John Thomas Strode, Maysville, Ky.; Jefferson Medical College, 1862; Pulte Medical College, Cincinnati, 1879; aged 81; died December 24 from cerebral hemorrhage.

Walter Louis Havens, Chester Depot, Vt.; College of Physicians and Surgeons in the City of New York, 1885; aged 58; died December 7, from tuberculosis.

Paris Garner Clark, Unadilla, N. Y.; Bellevue Hospital Medical College, 1868; aged 74; for many years a member of the local school board; died December 21.

William A. Brown, Louisville, Ky.; Meharry Medical College, Nashville, Tenn., 1892; aged 58; a colored practitioner; died October 19, from cirrhosis of the liver.

James L. Holden, Zanesville, Ohio; Medical College of Ohio, Cincinnati, 1882; aged 61; mayor of Zanesville in 1901 and 1902; died December 20, from nephritis.

Duane P. Andrus, St. Louis; American Medical College, Eclectic, St. Louis, 1883; aged 69; was found dead in his room, December 16, from gas asphyxiation.

Marion Cooper Geiger, Polytechnic, Texas; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1881; aged 66; died December 26, from heart disease.

Ella Ridgway Ziegler • Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1874; aged 74; died December 30, from cerebral hemorrhage.

Thomas M. Dromgold, Ottawa, Ill.; Eclectic Medical Institute, Cincinnati, 1878; aged 71; in Ryburn Hospital, Ottawa, December 21, from cerebral hemorrhage.

William Delay • Rome, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1881; died at Selma, Ala., December 7, from cerebral hemorrhage.

Levi N. Smith, Western, Neb.; Kentucky School of Medicine, Louisville, Ky., 1881; aged 65; died December 19, as the result of an automobile accident.

Davis A. Hogue • Altoona, Pa.; Jefferson Medical College, 1875; aged 65; died in Mercy Hospital, Altoona, December 18, from pulmonary embolism.

John Franklin Bradshaw, Lincoln, Neb.; Rush Medical College, 1879; aged 63; also a druggist; died December 19, from gangrene of the lungs.

Helen Grant Winn Zimdars, San Francisco; Cooper Medical College, San Francisco, 1897; aged 50; died December 25, from angina pectoris.

William E. Robinson, Rapid City, S. D.; Louisville (Ky.) Medical College, 1894; aged 48; died December 3, from pulmonary tuberculosis.

Sylvester Bronson Moon, Wilmington, Ohio; Miami Medical College, Cincinnati, 1872; aged 84; died December 21, from senile debility.

Andrew P. Davis, Los Angeles; Rush Medical College, 1867; Pulte Medical College, Cincinnati, 1877; aged 84; died December 19.

John F. Finley, Palmyra, Ind. (license, Indiana, 1897); aged 72; a practitioner for forty years; died December 25, from heart disease.

Stanley Wheelock, Quincy, Ill.; Kentucky School of Medicine, Louisville, 1893; aged 48; died November 22, from endocarditis.

Elisha J. Graham, Hodgenville, Ky.; University of Louisville, Ky., 1866; aged 80; a veteran of the Civil War; died December 24.

T. F. Donaldson, Knoxville, Tenn. (license, Tennessee, 1889); aged 70; died December 15 from pulmonary hemorrhage.

John Loomis, Jeffersonville, Ind. (license, Indiana, 1897); aged 99; a practitioner since 1860; died December 22.

David Norwood, Esperance, N. Y.; Albany (N. Y.) Medical College, 1867; aged 86; died November 24.

Jeremiah Roberts, Holton, Ind. (license, Indiana, 1897); aged 81; died November 19.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

SINGLETON'S EYE OINTMENT AND OTHER NOSTRUMS

The letter quoted below, from a layman in Oregon, is typical of those received by the Propaganda department from the general public. It is reproduced and answered because, in the answering, certain facts may be brought out that may be of interest to the medical profession.

"In looking over and re-reading your valuable work 'Nostrums and Quackery' I see no mention made of the alleged three-hundred-year-old British eye remedy, 'Singleton's Eye Ointment' nor 'Congreve's Elixir for Consumption.' Neither is the analysis of Swift's S. S. S. Remedy given nor 'Absorbine'; not a word about the remedies of Dr. Miles of Elkhart—his 'Nervine,' 'Anti-Pain Pills' and 'Heart Cure'; nor the 'Dr. Blosser Catarrh Remedy Company' of Atlanta, Ga. I should like to know the composition of the above mentioned remedies.

"How much I would like to see you organize a great campaign and print large bills exposing these frauds and have them on bill-boards in cities and your information distributed in form of pamphlets from house to house.

"In 'Nostrums and Quackery' you do not mention the 'Enk Tissue Remedies' nor 'Bon Opto' for the eyes. What is the composition of 'Tanlac' put up by the Cooper Medicine Company and 'Yellow Minyol' for the scalp put out by the Blackburn Products Company"

"Singleton's Eye Ointment" is not dealt with in "Nostrums and Quackery" because the stuff has but a limited sale in the United States; it is a British nostrum. It was analyzed by the chemists of the British Medical Association in 1909 who reported it to be essentially a mixture of lard, Japan wax and purified coconut oil with 4 per cent. of beeswax and 7.4 per cent. of red mercuric oxid. This analysis is recorded in Street's book "The Composition of Certain Patent and Proprietary Medicines" published by the American Medical Association. "Congreve's Elixir for Consumption" was also omitted from "Nostrums and Quackery" because the stuff is sold almost entirely in the British Isles or British possessions. It, too, has been analyzed by the chemists of the British Medical Association, who reported the presence of over 28 per cent. of alcohol by volume with only 2.6 per cent. of total solids, of which about 1 per cent. was sugar and 0.5 per cent. resinous constituents, with a little tannin, coloring matter and extractives. This formula also is given in Street's book.

"S. S. S." or "Swift's Sure Specific" is not discussed in "Nostrums and Quackery" (which came from the press in January, 1913) but is dealt with in more recent publications. An article on the product will be found in the pamphlet "Miscellaneous Nostrums."² In the same pamphlet will be found articles on "Absorbine," "Miles' Heart Treatment" (with incidental mention of "Miles' Anti-Pain Pills") "Bon Opto" and "Tanlac." "Miles' Nervine" is the subject of an article in the pamphlet "Epilepsy Cures,"³ while the composition of "Yellow Minyol" as found by the chemists of the Connecticut Agricultural Experiment Station is given in the pamphlet "Cosmetic Nostrums" also published by the Association.

The Blosser concern was dealt with by Mr. Adams in his "Great American Fraud"⁴ series (reprinted by the Association); the report of the North Dakota state chemists to the effect that this "catarrh remedy" is a mixture of chamomile flowers, aniseed, cubeb and pepper, is briefly quoted in Street's book.

The "Enk Tissue Remedies," while on record in the files of the Propaganda department, have seemed to constitute

too insignificant a piece of quackery to warrant the preparation of any article on them. While the Association does not have large posters on the bill-boards exposing the nostrum evil, it does have on sale educational posters on the subject and these are used to no small extent by individuals and organizations interested in bringing home to the public the menace of the nostrum. While, too, the Association does not distribute its pamphlets on the nostrum evil and quackery from house to house, nevertheless, in the past few years over a million pamphlets and books dealing with this subject have been put in the hands of the public.

KLINE'S NERVE RESTORATIVE

A physician in South Carolina, writes:

"I am anxious to learn the chemical composition or formula of 'Kline's Nerve Restorative'; also its therapeutic properties, if any. I was consulted recently by a patient regarding the preparation and, unfortunately, could only inform the patient—to quote a recent and very pertinent editorial in a most valuable medical journal—that possibly it was a preparation 'founded on 5 per cent. banalities of elementary science and 95 per cent. of pseudo-scientific flapdoodle,' and was not noted for any special therapeutic properties."

"Kline's Nerve Remedy" is one of a group of alleged epilepsy cures investigated by the Propaganda department and analyzed by the A. M. A. Chemical Laboratory in 1915. At that time it was reported, of the Kline nostrum, that: "Essentially, each 100 c.c. of the solution contains approximately 8.7 gm. ammonium bromid, 9.2 gm. potassium bromid and 8.0 gm. sodium bromid. Calculating from the bromid determinations each meal-time dose, one teaspoonful (1 fluidram), contains the equivalent of 17.2 grains potassium bromid, and each daily dose (5 teaspoonfuls) corresponds to 87.0 grains potassium bromid." The article on Kline's remedy, as well as the articles on other so-called epilepsy cures, have been brought together in one pamphlet ("Epilepsy Cures," price 10 cents) prepared and issued by the Propaganda department of THE JOURNAL.

Correspondence

MEDICAL VETERANS OF THE WORLD WAR

An Appeal to Medical Members of Selective Service Boards

To the Editor:—Immediately on the termination of hostilities in November, 1918, members of the medical profession on active service in Washington recognized the need of an organization to perpetuate the principles and fellowships developed during the war. A committee was therefore formed, which was representative of those governmental services—including the Provost Marshal General's Office—which were directly associated with the selection and administration of the armed forces of the United States. This committee formulated a constitution and by-laws which were adopted by the newly formed society at its first annual meeting, held at Atlantic City in June, 1919, in connection with the meeting of the American Medical Association. The society was tentatively named the Medical Veterans of the World War.

The qualifications set forth in the constitution provide that, in addition to men of the military, naval and public health services, the following are eligible to membership, namely, all medical members and medical examiners of Local, Medical Advisory and District Boards, officially appointed by the President of the United States, the Provost Marshal General, or the governors of the various states; also, additional examining physicians who were appointed by the President of a Local or Medical Advisory Board and vouched for by the medical aide to the governor.

When the armistice became effective, there were about 25,000 physicians who were associated with the operations of the Selective Service, in one or other of the capacities just cited. The personal and official relationships formed in

1. Street, J. P.: The Composition of Certain Patent and Proprietary Medicines, Chicago, American Medical Association, price \$1.25 postpaid.

2. Miscellaneous Nostrums: Chicago, Am. Med. Assn., price 20 cents.

3. Epilepsy Cures: Chicago, Am. Med. Assn., price 10 cents.

4. Adams, S. H.: Great American Fraud, Chicago, Am. Med. Assn., price 25 cents.

their activities were of so binding a character that medical men thus engaged were conscious of a strong bond of fellowship. It would be a great pity if the fine sentiments and comradeships engendered by the work should cease to be, through lack of opportunity for their continued expression. The society of Medical Veterans of the World War fills the need ideally, and it is felt that all medical men who were associated in the great and eminently successful work of the Selective Service should identify themselves with this organization.

The next annual meeting of the society will be held at New Orleans, April 27, the first day of the meeting of the American Medical Association. The dues are negligible—only one dollar with the application. The secretary-treasurer is Col. F. F. Russell, M. C., U. S. Army, Army Medical School, Washington, D. C. The president is Dr. Victor C. Vaughan, Ann Arbor, Mich.; the vice president is Admiral Stitt, and the trustees are Col. F. A. Winter and Drs. James C. Perry, John M. Dodson, George E. Brewer, Hubert Work and Joel E. Goldthwait.

F. R. KEEFER, M.D., Carlisle, Pa.

Colonel, M. C., U. S. Army; Late Chief, Medical Division, Provost Marshal General's Office.

[COMMENT.—According to the report of Col. F. F. Russell, secretary, on December 1 there were 2,399 members of the Medical Veterans of the World War, distributed as follows:

1. Medical Corps, U. S. Army	1,019
2. Medical Corps, U. S. Navy	41
3. Medical Corps, U. S. P. H. S.	57
4. Contract Surgeons, U. S. Army	81
5. Acting Asst. Surgeons, U. S. P. H. S.	43
6. Local Boards	491
7. Medical Examiner, Local Board	162
8. Medical Advisory Board	505
Total	2,399

The insignia which the badge committee has reported on is now being manufactured, and will be ready for distribution to the members within a short time.—Ed.]

"Medical Veterans of the World War" Offers Opportunity for Constructive Work

To the Editor:—Would that the letter of the Surgeon-General of the Army (THE JOURNAL, Jan. 10, 1920) might be placed in the hands of every medical officer who served in the Medical Reserve Corps.

The Surgeon-General has struck at the very crux of the matter: Instead of criticism and fault finding, what is needed is united support to prevent a recurrence of much of the inefficiency of which many of us were witnesses. You cannot make an army medical officer out of a civilian practitioner over night. If we suffered from unpreparedness, we have no one to blame but ourselves. It is our duty to see that it does not recur. This can be accomplished only through education, not through carping criticism. We all have our story to tell of those under us—and by those over us. I, who served as a divisional instructor, might add much which would not appear complimentary, but such observations would profit little unless constructive in character.

The skilful operator who may have filled an important chair in a teaching institution or a medical internist of equal reputation may utterly fail in rendering efficient service in the field. Other qualifications in addition are necessary to produce an efficient army officer. The failure on the part of many to realize this phase of the situation was the cause of much heart burning. The time has come to cease complaining and to join hands in upholding the efforts which that small body of medical officers of the regular Army tried to exert in attempting to overcome a condition well nigh unsurmountable (450 medical officers for an army of 2,000,000 men). Those of us conversant with the conditions which then existed realize that in no better way can we aid in preventing a recurrence than in supporting whole heartedly the efforts of those who wish to make the organization of the Medical Veterans of the World War a powerful force in preparing for any future emergency.

JOSEPH LEIDY, M.D., Philadelphia.

"ALLEGED PLACENTAL FUNCTIONS"

To the Editor:—The communication from Dr. Robert T. Frank (THE JOURNAL, Jan. 3, 1920, p. 47) contains some misconceptions of my interpretations of the results of the work that has been done in the studies directed toward ascertaining whether or not the placenta can be classified among the glands of internal secretion, as published in *Endocrinology* (3: 307 [July-Sept.] 1919). This article was merely intended as a review of the work to date in as brief a manner as possible. It was therein distinctly stated that "a retrospective analysis of the work undertaken, however, reveals four fairly distinct nuclei of attention," and a discussion was made of these four fields of effort, namely: (1) the possibility that the placenta produces an internal secretion concerned in eclampsia; (2) the possibility that the placenta produces an internal secretion effecting the mammary hyperplasia of pregnancy; (3) the possible galactogogic activity of the placenta, and (4) placental products considered as stimuli to growth. Each one of these phases of possible function was taken up seriatim and individually, and the statement that I have fallen into the error of not differentiating between hyperplasia or galactogogic stimuli or processes indicates a misreading of what I said, as any one can verify by reading the original article. Moreover, a wrong impression is given, as frequently happens when partial quotations are made. That I definitely assigned a finality to the bedside observations is implied by the quotation given by Dr. Frank. If he had quoted the following sentence, this implication would not have seen print. The next sentence is as follows:

It is of course obvious that we are here dealing with a condition much different from that occurring during pregnancy and that the negative results may mean little or nothing as evidence toward the part played by the placenta in *pregnancy hyperplasia*; nevertheless, the validity of the interpretation is on a par, until disproved, with that given from the work on virgin animals.

As to the effect of the ingestion of desiccated placenta on the growth of breast-fed infants, the observations of Van Hoosen, Cornell, and McNeile and myself have yet to be disqualified by experimental work.

Now as to my reading into the results that the placenta *does* of a fact produce an intra-uterine growth-promoting hormone: Such was neither my intention nor my aim. The statement that "it is not illogical to suppose that the placenta in utero produces a substance acting as a stimulus to fetal growth" should to any thoughtful reader convey what it was intended for, the idea, purely speculative, that such a possibility might exist, and pointing out a possible field of investigation. Its intention should be particularly obvious, since I did not make any references to any work that had been carried on tending to throw light on the possibility.

FREDERICK S. HAMMETT, Ph.D., Philadelphia.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

GLUE FOR TRACTION IN FRACTURES

To the Editor:—Please inform me concerning Sinclair's formula for a glue for traction in fractures.

W. E. WHALEN, M.D., Ogden, Utah.

ANSWER.—According to Sinclair's formula, 4 ounces of glue are placed in 4 pounds of cold water and left in a cool place for twelve hours. If the glue dissolves, it is bad; if it is coherent and gelatinous, weighing 8 ounces, it is good; if coherent and gelatinous, weighing 16 ounces, it is very good; if coherent and gelatinous, weighing 20 ounces, it is excellent. Fifty parts of good glue are soaked for twelve hours in water, 50 parts; glycerin, 4 or 6 parts, and menthol, 1 part, and then melted on a water bath. After neutralizing to litmus with sodium hydroxid, as commercial glue at times contains free hydrochloric acid, there are added 4 parts in summer and 5 parts in winter of glycerin and 1 part of

menthol. Frequent heating evaporates the water, which should be added from time to time. When reheated many times, adhesive power is lost. The technic is as follows:

1. The skin is not shaved.
2. Wash the skin with soap and hot water which contains about 4 drams of washing soda to the pint, to convert the oil of the skin into soap, as glue will not adhere to a greasy surface.
3. Dry the skin.
4. Apply the warm glue evenly, brushing all the hairs of the limb in an upward direction.
5. Keep a tension on the gauze all the time; bring it quickly but carefully into contact with the limb (inner and outer surface), and apply neatly a loose woven bandage, starting a hand's breadth above the malleoli up to the joint.
6. When dry, apply traction.
7. The adhesive can be made waterproof with a 2 per cent. solution of potassium bichromate applied in the dark and then exposed to the light, or by means of liquor formaldehydi.)
8. The extension must always be applied very carefully, whether with Maw's elastic cotton net or with gauze.
9. The extension must be changed at once if the patient complains of a tickling or burning sensation under it, but it generally requires changing about the tenth, twentieth or fortieth day.

In THE JOURNAL, Sept. 27, 1919, p. 973, Dr. W. F. Cunningham describes a new adhesive material for this purpose, which he believes superior to the Sinclair formula. It consists of a solution of celloidin in acetone, which is prepared as follows:

The required amount of celluloid scrap and acetone are placed in a dry, clean, wide-mouthed bottle and securely stoppered. The bottle is then shaken or agitated at intervals, and the solution is ready for use in from twenty-four to forty-eight hours. When properly made, it should be an almost clear, homogeneous, syrupy fluid.

In the experiments, no careful preparation of the skin was made. It should, however, be absolutely dry; and the preliminary use of a few cubic centimeters of acetone on the region to be employed may aid in this respect, but is not necessary. A layer of celluloid solution is rapidly applied by means of a small, stiff brush. The quantity should be sufficient to soak through the strip on which traction is to be applied, and a thin coating should be applied externally to get out all the wrinkles and air bubbles. Canton flannel is the best material for strips, but a double layer of gauze or muslin that is neither too hard nor too finely woven may be used.

Iodin and also picric acid and alcohol should be avoided as far as possible on areas to which any type of adhesive is to be applied. Both these drugs increase exfoliation, and we well know the reaction of certain skins to the former. We believe, with Sinclair, that the part should not be shaved before adhesive material is applied, for the hairs, if abundant, increase the efficiency of the adhesive, like hair in plaster. If there is delay in putting on the strip, the skin should be recoated, for it dries out in a thin, flexible film in a minute or two. The application of a circular gauze bandage over cotton increases the effectiveness of adhesion and should be used. It is needless to state that the solution is combustible; therefore it should not be heated, and containers should be so labeled.

COMPARATIVE FOOD VALUES OF BUTTER AND OTHER FATS

To the Editor:—Can you give a comparison in food values and in digestibility of cocomargarine; olive oil and olcomargarine as compared with butter? With present prices for real butter, many are compelled to seek substitutes which may or may not be more economical.

J. TRACY MELVIN, M.D., Porterville, Calif.

ANSWER.—The heat values of butter and other fats are fairly constant; the values given are: for butter fat, 9,312; for fat of animal tissue, 9,372, and olive oil, 9,384 calories per gram. The nutritional value of a food is, however, also determined by the presence or absence of certain vitamins, as for instance, fat-soluble A, normally present in butter. The fat-soluble accessory growth substance is present in beef fat and "oleo-oil," and margarins prepared on such a basis are probably the nutritive equivalent of butter. Coconut oil, cottonseed oil, peanut oil, olive oil, and nut and vegetable oils in general contain little or none of this accessory substance, and margarins prepared from these are not the nutritive equivalent of butter. With allowance for metabolic products, the coefficients of digestibility have been found to be: for butter fat, 97 per cent.; for beef fat, 93; for olive oil, 97.8, and for coconut oil, 97.9 per cent.

For more complete details the following contributions may be consulted:

LITERATURE ON NITROUS OXID-OXYGEN ANESTHESIA

To the Editor:—I am desirous of obtaining all the literature in the past two years (American) on general anesthesia with nitrous oxide and oxygen.

V. D. THOMAS, M.D., Bloomington, Ill.

ANSWER.—In the Quarterly Cumulative Index for 1918, under the heading "Anesthesia," appear the following references:

- Nitrous oxid analgesia in obstetrics (J. C. Hoag) *Illinois M. J.* 33: 324 (April) 1918.
—in labor (L. C. Redmon) *Kentucky M. J.* 16: 499 (Nov.) 1918.
—in production of painless childbirth (M. Salzer) *Ohio State M. J.* 14: 406 (July) 1918.
—new inhaler for (A. H. Miller) *J. A. M. A.* 71: 109 (July 13) 1918.
—on possibility of mixing air in lungs with foreign air, especially as it is used in Krogh and Lindhard's nitrous oxid method (C. Sonne) *J. Physiol.* 52: 75 (July) 1918.
Nitrous oxid-oxygen, comparative dangers and availability of (J. R. McCurdy) *Am. J. S. (anesthesia supp.)* 32: 19 (Jan.) 1918.
—and anaesthol sequence in oral surgery (C. H. Sanford) *Ann. Surg.* 67: 462 (April) 1918.
—changes produced in blood by nitrous oxid-oxygen anesthesia (T. D. Casto) *Am. J. S. (anesthesia supp.)* 32: 42 (April) 1918.
—in labor (C. E. Turner and W. I. Jones) *Am. J. S. (anesthesia supp.)* 32: 52 (April) 1918.
—in obstetrics (C. S. Fleming) *W. Va. M. J.* 12: 246 (Jan.) 1918.
—simple apparatus for (A. S. Wilson) *Brit. M. J.* 1: 78 (Jan. 19) 1918.
Nitrous oxygen, experimental researches in warming of nitrous oxygen for anesthesia (P. Cassidy) *Am. J. S. (anesthesia supp.)* 32: 46 (April) 1918.

In the issue for January-September, 1919, under the same heading, appear:

- Nitrous oxid analgesia in labor (R. C. Coburn) *New York State J. Med.* 19: 37 (Feb.) 1919.
—in labor (R. S. Allison) *Northwest Med.* 18: 9 (Jan.) 1919.
Nitrous oxid-oxygen analgesia in obstetrics (A. L. Smith) *Nebraska M. J.* 4: 54, 1919.
—cesarean section and obstetric observation under nitrous oxid-oxygen (E. I. McKesson) *Am. J. Surg. (anesthesia supp.)* 33: 84 (July) 1919.

—Study of blood pressure changes during (W. B. Davis and W. H. Spencer) *Therap. Gaz.* 43: 82 (Feb.) 1919.

RESTORATION OF MENSTRUAL FUNCTION LOST AFTER RADIUM TREATMENT

To the Editor:—Can you give me any treatment for the restoration of the menstrual function in a young person after it has been partially stopped for a year from radium treatment, or inform me of literature on the subject?

J. A. VALENTA, M.D., Lake City, Iowa.

ANSWER.—In articles on the treatment of uterine fibroids or menorrhagia by radium it has been noted that many patients, after a cessation of menstruation from nine months to two years, begin spontaneously to menstruate again. This may occur even after the third year. It also seems likely that the giving of corpus luteum alone or in combination with hypophysis extract (pituitary solution) can hasten the return. If, however, the original radiation has been intense enough to destroy all the primordial follicles of the ovary, no return of menstruation can be expected.

A Swedish View of the Council on Pharmacy and Chemistry.—The leading, in fact, the only article in *Hygiea*, Oct. 16, 1919, is an account by Anderson-Tesch of his five months in the United States as delegate sent by the Association of Swedish Manufacturing Chemists to study the chemical industry in America and its development during the war. Incidentally he was much impressed with the medical institutions of this country, as he relates with minute detail, especially the way in which the physical examination of the recruits was managed and recorded. He devotes several pages to describing in detail the work of the Council on Pharmacy and Chemistry which, he says, is "undoubtedly the most energetic and well planned work for control of non-official remedies. It was realized by the initiative of the American Medical Association, America's largest and most esteemed medical association."

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

ALASKA: Juneau, Mar. 2. Sec., Dr. L. O. Sloan, Juneau.
CALIFORNIA: Los Angeles, Feb. 16-19. Sec., Dr. Chas. B. Pinkham, 906 Forum Bldg., Sacramento.
ILLINOIS: Chicago, Mar. 1-3. Director, Mr. Francis W. Shepardson, Springfield.
INDIANA: Indianapolis, Feb. 10-13. Sec., Dr. W. I. Gott, 84 State House, Indianapolis.
KANSAS: Topeka, Feb. 10. Sec., Dr. H. A. Dykes, Lebanon.
NATIONAL BOARD OF MEDICAL EXAMINERS: St. Louis and Chicago, Feb. 18-25. Sec., Dr. J. S. Rodman, 1310 Medical Arts Bldg., Philadelphia, Pa.
NEW YORK: New York City, Albany, Buffalo, Jan. 27-31. Asst. Professional Examinations, Mr. H. J. Hamilton, Albany.
VERMONT: Burlington, Feb. 10-12. Sec., Dr. W. Scott Nay, Underhill.
WYOMING: Thermopolis, Feb. 2-4. Sec., Dr. J. D. Shingle, Cheyenne.

ANNUAL CONFERENCE ON MEDICAL EDUCATION AND LICENSURE

The next conference on medical education and licensure will be held, March 1, 2 and 3, at the Congress Hotel, Chicago, under the auspices of the Council on Medical Education of the American Medical Association, the Association of American Medical Colleges, and the Federation of State Medical Boards of the United States. Instead of the three separate disjointed programs heretofore held, there will be a single program by which conflicts and duplications will be avoided, papers will be more carefully selected, and discussions will be more effectively directed. The program as now arranged is as follows:

Introductory Remarks by Dr. Arthur Dean Bevan, chairman of the Council on Medical Education; Dr. George Blumer, president of the Association of American Medical Colleges, and Dr. David A. Strickler, president of the Federation of State Medical Boards.
"Present Status of Medical Education," Dr. N. P. Colwell, secretary of the Council on Medical Education.

Symposium on "The Needs and Future of Medical Education," Dr. George E. Vincent, president of the Rockefeller Foundation, New York. The following also have been invited: Dr. Ray Lyman Wilbur, president of Leland Stanford University. Dr. Henry S. Pritchett, president Carnegie Foundation for the Advancement of Teaching, New York. Dr. Harry Pratt Judson, president University of Chicago. Mr. Abraham Flexner, secretary of the General Education Board, New York.

"The Larger Function of State University Medical Schools," Dr. Walter A. Jessup, president of the State University of Iowa, Iowa City.

"Full-Time Teachers in Clinical Departments," Dr. William Darrach, dean of Columbia University College of Physicians and Surgeons, New York.

"Research in Medical Schools, Laboratory Departments," Dr. Oskar Klotz, professor of pathology, University of Pittsburgh School of Medicine.

"Research in Medical Schools, Clinical Departments," Dr. G. Canby Robinson, dean, Washington University School of Medicine, St. Louis.

"Graduate Medical Instruction in the United States," Dr. Louis B. Wilson, Mayo Clinic, Rochester, Minn.

"Interallied Medical Relations; Qualifying Examinations, Licensure Requirements, Graduate Medical Education," Dr. Walter L. Biering, secretary of the Federation of State Medical Boards, Des Moines, Iowa.

"Interstate Relations in Medical Licensure," Francis W. Shepardson, director of the Department of Education and Registration of the State of Illinois, Springfield.

"Essential Improvements in Medical Licensure," Dr. John M. Baldy, president of the Pennsylvania Bureau of Medical Education and Licensure, Philadelphia.

Reports on Medical Teaching from the Committee on Medical Pedagogy of the Association of American Medical Colleges.

Remarks by the chairman of the committee, Dr. W. S. Carter, dean, University of Texas, Department of Medicine, Galveston.

Anatomy: Dr. Charles R. Bardeen, dean, University of Wisconsin Medical School, Madison.

Histology and Embryology: Dr. F. C. Waite, secretary, Western Reserve University School of Medicine, Cleveland.

Physiology: Dr. E. P. Lyon, dean, University of Minnesota Medical School, Minneapolis.

Biochemical Chemistry: Dr. Otto Folin, professor of biologic chemistry, Medical School of Harvard University, Boston.

Pharmacology: Dr. C. W. Edmunds, assistant dean, University of Michigan Medical School, Ann Arbor.

Pathology: Dr. James Ewing, professor of pathology, Cornell University Medical School, New York.

Bacteriology and Parasitology: Dr. A. I. Kendall, dean, Northwestern University Medical School, Chicago.
Public Health and Preventive Medicine: Dr. Victor C. Vaughan, dean, University of Michigan Medical School, Ann Arbor.

The afternoon of Wednesday, March 3, will be devoted to the separate business sessions of the three organizations. It is expected that the conference will be immediately followed by the annual meeting of the American Conference on Hospital Service.

Montana April Examination

Dr. S. A. Cooney, secretary of the Montana Board of Medical Examiners, reports the written examination held at Helena, April 1-3, 1919. The examination covered 10 subjects and included 50 questions. An average of 75 per cent. was required to pass. Of the 15 candidates examined, 12 passed and 3 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
George Washington University	(1907)	79.8
College of Physicians and Surgeons, Chicago	(1901)	75.6
Rush Medical College	(1919)	75.7, 83.9
Kansas Medical College	(1911)	79.1, (1913) 79.7
College of Physicians and Surgeons, Baltimore	(1912)	78.3
Washington University	(1911)	82
John A. Creighton Medical College	(1913)	82, (1919) 79.9
Jefferson Medical College	(1904)	77.4
Medico-Chirurgical College of Philadelphia	(1900)	77.9

College	FAILED	Year Grad.	Per Cent.
Loyola University	(1917)	67.1
Kansas City Hahnemann Medical College	(1905)	71.5
Ensworth Medical College	(1909)	38.1

*Received certificate for four years' work; will receive M.D. degree after completing his intern year.

Arkansas Eclectic May Examination

Dr. Claude E. Laws, secretary of the Arkansas Eclectic Board of Medical Examiners, reports the written examination held at Little Rock, May 13-14, 1919. The examination covered 12 subjects and included 120 questions. An average of 75 per cent. was required to pass. Thirty-four candidates were examined, all of whom passed.

College	Year Grad.	No. Licensed
Hospital Medical College, Atlanta	(1909) 1
Bennett Medical College	(1909) 1
American Medical College	(1902) 1
Kansas City College of Med. and Surgery	(1918) 1, (1919) 30, 31

New Jersey June Examination

Dr. Alexander MacAlister, secretary of the New Jersey Board of Medical Examiners, reports the written examination held at Trenton, June 17-18, 1919. The examination covered 9 subjects and included 90 questions. An average of 75 per cent. was required to pass. Thirty-six candidates were examined, all of whom passed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Georgetown University	(1917)	88
Howard University	(1916)	85.7
Baltimore Medical College	(1912)	81.4
Johns Hopkins University	(1917)	91.3
University of Maryland	(1917)	86.3
Tufts College Medical School	(1916)	82
Columbia University	(1915)	83.5
New York Homeo. Med. Coll. and Flower Hosp.	(1918)	86.7
University and Bellevue Hospital Medical College	(1918)	86.6, 88.8, 89.2
Hahnemann Medical College and Hospital of Philadelphia	(1917)	80.7, (1918) 87.1
Jefferson Medical College	(1915) 82.2, (1916) 83.4, 85.4, (1917) 83.5, 84.1, 84.8, 87.8, (1918) 82.2, 83.3, 84.6, 85.4, 85.5, 86.2	
Medico-Chirurgical College of Philadelphia	(1916)	79
University of Pennsylvania	(1917) 82.7, 87.1, (1918) 83.1, 85.5, 88.4	
Vanderbilt University	(1912)	86
Fort Worth School of Medicine	(1902)	83.6
University of Virginia	(1917)	90.5
Queen's University	(1918)	83.6

Dr. MacAlister also reports that ninety-eight candidates were licensed by reciprocity from Jan. 1 to July 5, 1919. The following colleges were represented:

College	LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
University of California	(1907)	New York
Yale University	(1912)	New York
Columbian University	(1902)	New York
George Washington University	(1916)	Dist. Colum.
Howard University	(1917, 2)	Dist. Colum.
Kentucky School of Medicine	(1894, 2)	Penna.
University of Louisville	(1915)	Kentucky

Baltimore Med. Coll. (1896) Pennsylvania, (1905), (1913) New York
Univ. of Maryland (1916, 2) New York, (1916), (1917) Maryland
Tufts College Med. School (1910) Massachusetts, (1916) New Hamp.
Missouri Medical College (1889), (1896) New York
Washington University (1897) Connecticut
Dartmouth Medical School (1901) New Hamp.
Albany Medical College (1905), (1908), (1915) New York
Columbia University (1885) Oregon, (1898) New York, (1899) Con-
necticut, (1903), (1914), (1917), (1918, 4) New York.
Cornell University (1911) New York
Fordham University (1914), (1918, 3) New York
Long Island College Hospital (1898), (1914, 2), (1915, 2) New York
New York Homeopathic Medical College and Flower Hospital (1915),
(1916, 2), (1917, 2), (1918) New York, (1918) Illinois.
University and Bellevue Hospital Medical College (1912) New York
(1913) Connecticut, (1914) (1916, 2), (1917, 2), (1918, 7) New York
University of Buffalo (1905), (1908), (1913) New York
University of the City of New York (1890) Illinois, (1894) New York
Medical College of Ohio (1890) Kentucky
Jefferson Medical College (1899), (1903) Pennsylvania, (1912), (1913)
New York, (1915) West Virginia, (1916) Delaware, Alabama, (1917)
New York.
Medico-Chirurgical College of Philadelphia (1903), (1911), (1913),
(1914) Pennsylvania.
University of Pennsylvania (1889), (1898), (1900, 2), (1916), (1917)
Pennsylvania.
Woman's Medical College of Pennsylvania (1915) Penna.
Temple University (1917) Penna.
University of Vermont (1904), (1908) Vermont
Medical College of Virginia (1915) Virginia, (1917) Maryland
Trinity Medical College (1900) New York
University of Munich (1892) New York
University of Naples (1896) Connecticut

Wisconsin June Examination

Dr. John M. Dodd, secretary of the Wisconsin State Board of Medical Examiners, reports the written and practical examination held at Milwaukee, June 24-26, 1919. The examination covered 18 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 16 candidates examined, 15, including 1 osteopath passed, and 1, an osteopath, failed. Six candidates were licensed by reciprocity. Seventeen candidates were licensed by virtue of a commission in the Medical Corps. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Northwestern University (1918), 83 (1919) 85, *86, 89.			
Rush Medical College (1919) *81, *84, 85.			
Washington University (1919) 77, 84, 87.			
Columbia University (1919)	88		
Jefferson Medical College (1919)	82		
Marquette University (1919)	79, 84		

College	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Georgetown University (1909)			Illinois
College of Physicians and Surgeons, Chicago (1904)			Illinois
Rush Medical College (1917), (1919)			Illinois
University of Illinois (1916)			Illinois
University of Louisville (1915)			Kentucky

College	LICENSED BY ENDORSEMENT OF CREDENTIALS	Year Grad.	Certificate from
University of Arkansas (1918)			U. S. Army
College of Physicians and Surgeons, Los Angeles (1912)			U. S. Army
Bennett Medical College (1915)			U. S. Army
Chicago College of Medicine and Surgery (1916), (1917)			U. S. Army
Northwestern University (1910), (1917)			U. S. Army
Rush Medical College (1915)			U. S. Army
University of Illinois (1914)			U. S. Army
St. Louis University (1910)			U. S. Army
Cleveland College of Physicians and Surgeons (1903)			U. S. Army
Jefferson Medical College (1916)			U. S. Army
University of Pennsylvania (1914, 2)			U. S. Army
Meharry Medical College (1915)			U. S. Army
University of Virginia (1916)			U. S. Army
Marquette University (1917)			U. S. Navy

* Received limited licenses pending completion of their hospital internship.

District of Columbia July Examination

Dr. Edgar P. Copeland, secretary of the District of Columbia Board of Medical Supervisors, reports the oral and written examination held at Washington, July 8-10, 1919. The examination covered 16 subjects and included 80 questions. An average of 75 per cent. was required to pass. Of the eighteen candidates examined, 15 passed and 3 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
George Washington University (1919) 75.3, 81.5, 81.7, 85.2, 85.7, 86.2, 91.1.			
Howard University (1918) 75.3, 83.5, (1919) 76.5, 82.1			
Harvard University (1917)	90.5		
Middlesex College of Medicine and Surgery (1918)	76.6		
University of Pennsylvania (1919)	90.2		
University of Tennessee (1918)	82.2		

College	FAILED	Year Grad.	Per Cent.
Howard University (1919)	64,		72.2
Columbus Medical College (1884)	60		

Book Notices

INDUSTRIAL MEDICINE AND SURGERY. By Harry E. Mock, B.S., M.D., F.A.C.S., Assistant Professor of Industrial Medicine and Surgery at Rush Medical College. Cloth. Price, \$10 net. Pp. 846, with 210 Illustrations. Philadelphia: W. B. Saunders Company, 1919.

The purpose of this book is to describe modern American efforts and methods directed to maintenance of health, conservation of man-power, and rehabilitation of the disabled in industry. The contents fall in six parts: industrial health service; prevention; industrial medicine; industrial surgery; compensation, insurance, and medicolegal phases; and reconstruction. At the end is a bibliography of the pertinent literature since 1916, but as the references are listed alphabetically according to authors' names the practical value of the bibliography is limited. The author reveals himself in this book as an able and skilful physician and surgeon, a successful administrator of large enterprises, and a forceful propagandist and promoter of the movement to conserve the health and strength of working men and women, and he has provided a useful work for many employers, health workers, and especially physicians attached to industries and concerned with the organization and development of the medical service. Throughout it is the busy executive officer who speaks rather than the careful and thoughtful scholar, and there is no lack of evidence in both text and arrangement of undue haste in preparation and failure carefully to consider relative values. Careful revision with merciless rejection of all unnecessary words and statements—and we were about to add chapters—would increase the value of the book; and it is hoped that the author soon may be called on to prepare a second edition, and that he then may have leisure to do himself more justice than it has been permitted him in the first issue.

TOWARDS RACIAL HEALTH. A Handbook on the Training of Boys and Girls, Parents, Teachers and Social Workers. By Norah H. March, B.Sc., M.R.San.I., with Foreword by J. Arthur Thompson, M.A., LL.D., Professor of Natural History in the University of Aberdeen. New American Edition with an Introduction by Evangeline W. Young, M.D. Cloth. Price, \$2 net. Pp. 320, with illustrations. New York: E. P. Dutton & Company, 1919.

Miss March's book is intended for the instruction of parents, teachers and social workers on sex education rather than for boys and girls. Evidently this subject has not been discussed in England to the extent that it has been in this country. The approach to the subject, as well as the discussion, is much more largely influenced by the biologic point of view than in most of our American books on sex hygiene, nearly a third of the book being devoted to the purely biologic side of sex development and reproduction. Although somewhat conservative, the book is scientifically sound. It is better adapted for the teacher and the parent of education and leisure than for the average reader. The carefully selected bibliography will be of assistance to those desiring to take up a further study of the subject.

OXFORD LOOSE-LEAF MEDICINE. Edited by Henry A. Christian and Sir James Mackenzie. Advance pages, Volume II. Part I. Paper. New York: Oxford University Press, 1919.

This part contains 115 pages on diseases of the heart, by Sir James Mackenzie, and thirty-four pages on asthma and hay-fever by I. Chandler Walker. Mackenzie's topics are symptoms; heart failure; the examination of the patient; myocardial affections; angina pectoris; exhaustion, palpitation and syncope; the soldier's heart; mechanical aids in examination; modified sounds of the heart; valvular diseases; prognosis, and treatment. It is significant of the change that has come over cardiology that the diseases of the valves are discussed in eleven pages. Not so very many years ago they would have taken a much larger proportion of space. Mackenzie's treatment of all these subjects is in his usual clear style with little citation of authority but with direct, blunt statement of facts based on his wide clinical experience. Walker has an unusually lucid, up-to-date discussion of asthma, concerning the nature of which his extensive researches have made him an expert.

SQUIBB'S MATERIA MEDICA, 1919 EDITION. A Complete Alphabetical List of the Squibb Products, including all the articles of the United States Pharmacopoeia (IXth Revision) and of the National Formulary (IVth, 1916, edition), together with the Non-Official Chemicals, Pharmaceutics and Newer Remedies in general use. By the Medical Department, E. R. Squibb & Sons. Cloth. Gratis. Pp. 544. New York: E. R. Squibb & Sons, 1919.

The text gives the official name of the drug, the English name, synonyms, botanic origin, habitat, part of plant used, description, chief constituents, official standards of purity and strength, dose, and list of official preparation, if any. It is to be regretted that the useless or little used drugs, such as cactus, celery, elder flowers, galega and horse-nettle are given the same prominence as those of recognized value. Some of the information concerning the drug constituents cannot be relied on, as it has evidently been compiled from dispensatories or other second-hand sources. For example, the statement is made under Sabal that the drug contains volatile oil. The researches of Mann and Lloyd have shown that the drug contains no volatile oil, although on standing alcoholic preparations may develop an ester which is volatile. The book should be useful to drug analysts, pharmacists and pharmacognocists.

Medicolegal

Death from Glanders Contracted Through Inhalation

(*Richardson v. Greenburg* (N. Y.), 176 N. Y. Supp. 651)

The Supreme Court of New York, Appellate Division, Third Department, holds, in answer to a question certified to it by the state industrial commission, that where an employee was required to lead a horse affected with glanders and during such time contracted the disease through inhalation of the bacteria, and died from the disease fourteen days thereafter, his death was not due to an accidental injury arising out of and in the course of his employment, within the meaning of the workmen's compensation law. The court says that compensation is payable by an employer only "for the disability or death of his employee resulting from an accidental personal injury," and that "injury" and "personal injury" are stated to "mean only accidental injuries arising out of and in the course of employment, and such disease or infection as may naturally and unavoidably result therefrom." The plain meaning of the words of the law, without the aid of judicial interpretation, induces the conclusion that the legislature intended to make compensatory no condition or death resulting from disease, unless the disease itself followed a traumatic injury or other injury not partaking of the nature of a disease. It is a matter of common knowledge that the conditions generally prevailing in cases of infectious disease are caused by poisons or toxins exuded by living organisms or bacteria present within the human body. Glanders cannot be differentiated from other diseases by the fact that ordinarily it is a disease which affects a horse rather than a human being, for it cannot matter whence the bacteria have proceeded which set up disease within the human body.

State Not Liable for Death of Militiaman from Inoculation

(*McAuliffe v. State* (N. Y.), 176 N. Y. Supp. 679)

The Court of Claims of New York, in dismissing a claim for damages for the death of a state militiaman from inoculation with an immunizing vaccine administered at one of the state's armories by a physician in charge of said armory, the vaccine used being alleged to have been impure, or the treatment improperly administered, says that states are not liable in damages for torts or wrongful acts committed by their agents or servants, unless such liability has been voluntarily assumed by act of the legislatures. This rule follows from the maxim of the English common law, "The king can do no wrong," and not alone from the other rule of the English common law that the sovereign cannot be sued without his consent. In organizing the national guard for

the public defense, the state is exercising one of the highest and most important of the attributes of sovereignty and of the functions of government in the interest of the public at large, and under such circumstances it cannot be held liable for the negligence of its agents or servants. Furthermore the state has by statute provided a tribunal and a method for affording relief to those of its soldiers who shall be wounded or incapacitated as a result of illness and for pensioning dependents of such soldier, including his widow, minor children, or dependent mother, in case he shall have died as the result of injuries received or from illness. The state having furnished such tribunal, and submitted such cases to it for its consideration, this court is denied jurisdiction to hear and determine such claims.

Award May Be Commuted When Operation Is Necessary

(*Jensen v. F. W. Woolworth Co.* (N. J.), 106 Atl. R. 808)

The Court of Errors and Appeals of New Jersey affirms a judgment approving of the commutation to the lump sum of \$1,247.25 of an award under the workmen's compensation act of \$1,410 that was payable in instalments of \$5 a week, when an employee had accidentally swallowed pins while assisting in trimming a show window, and a physician testified that there was a pin near the base of her brain and in his opinion an operation would have to be performed to save the woman's life; that she was in need of constant care and attention, and unless she received it, her life could not be saved. The court says that the workmen's compensation act of New Jersey provides that, as commutation is a departure from the normal method of payment, it is to be allowed only when it clearly appears that some unusual circumstances warrant such a departure. But, if to be bedridden, with the requirement of a surgical operation to save the patient's life, is not an unusual circumstance, and such a one as warrants commutation of future weekly payments into a lump sum, to enable the patient to procure the services of a surgeon and the proper medical attention and nursing, it is hard to conceive of circumstances that would call for the making of an order for commutation. Bearing in mind that it is the intention of the act that compensation payments are in lieu of wages, and are to be received by the injured employee in the same manner in which wages are ordinarily paid, that is, instalments; and while commutation is a departure from the normal method of payment, to be allowed only when it clearly appears that some unusual circumstances warrant it, the court thinks those circumstances were present in the case under consideration, namely, that the life of the employee appeared to be at stake, and that, at least in all probability, it could be saved only by a surgical operation, by the attendance of a physician, by nursing, and by medicines, all of which would require the expenditure of moneys, which the patient did not possess and could not raise. Nor was commutation in these circumstances to be defeated by the concluding provision of the statute that it shall not be made to enable the employee to satisfy a debt, or to make payment to physicians, lawyers or other persons.

Employer Not Liable for Negligence of Physician

(*Smith v. Buckeye Cotton Oil Co.* (Ark.), 212 S. W. R. 88)

The Supreme Court of Arkansas affirms a judgment on a verdict directed in favor of the defendant in this case where the plaintiff alleged that while he was employed by the defendant he had his fingers crushed, and was directed to go to a physician employed by the defendant to treat his injured employees, and that this physician treated his injuries so carelessly and negligently that the amputation of all the fingers on the injured hand became necessary. The court says that the testimony in the case appeared to have been addressed to the proposition that the physician was negligent, and that the defendant was liable for this negligence because it directed the plaintiff to consult him. There was no intimation in the pleadings that the defendant was negligent in selecting a physician, nor was there any testimony to that effect unless it was by inference that the defendant was negligent through having employed a negligent

physician. The court had a case, therefore, in which the pleadings and proof showed only that an injured employee was directed to, and placed in charge of, a physician who was guilty of negligence in his treatment of the case. But this allegation and this proof did not make a case for the jury. Where the employer owes his employee the duty of furnishing medical attention, or undertakes to discharge that duty, he does not become liable for the physician's negligence or lack of skill, but is liable only when he fails in the discharge of his duty to exercise ordinary care to select a physician possessing the requisite skill and learning and one who would give the patient the attention and treatment which the case requires.

Ordering Physical Examination Partly Discretionary

(*Titus v. City of Montesano (Wash.)*, 181 Pac. R. 43)

The Supreme Court of Washington holds that there was no error in this personal injury case in denying the defendant's motion for an order directing the plaintiff to submit to a medical examination for the purpose of determining the extent of her alleged injury and for the purpose of qualifying the witnesses of the defendant to give testimony in the cause. The court says that the statute of that state relating to such examinations provides that, on or before the trial of any action brought to recover damages for injury to the person, the court before which such action is pending may from time to time, on application of any party therein, order and direct an examination of the person injured as to the injury complained of by a competent physician or physicians, surgeon or surgeons, in order to qualify the person or persons making the examination to testify in such case as to the extent, nature and probable duration of the injury complained of. This statute is not mandatory. It provides that the court "may . . . order and direct" a physical examination, and leaves something to the discretion of the court. When the motion was made in this instance, no issue had been framed as to the extent of the plaintiff's injuries, and no showing as to the necessity for such an examination accompanied the motion. It was not the purpose of the statute needlessly to harass a litigant, and, unless it is shown that some necessity exists for the examination at the time the application is made, the appellate court cannot say it is an abuse of discretion to deny it.

Testifying Indirectly to Privileged Communications

(*McGinty v. Brotherhood of Railway Trainmen (Wis.)*, 172 N. W. R. 714)

The Supreme Court of Wisconsin holds, in this action brought by a mother on a policy of insurance issued on the life of her son after he had stated in his application for the insurance that his father had never had any cancerous disease, that there was no error in refusing to permit a physician to testify that he told the mother, at the time of his professional visit, that her husband had cancer. The court says that the mother had been examined adversely, and testified that the physician did not make such statement to her. A portion of the physician's deposition was then offered in evidence to show that he had made such statement. The trial court excluded the testimony, and the supreme court sees no theory on which the testimony could be received. It certainly could not be probative evidence of the fact that the father in fact had cancer. The physician could not testify to that fact. His knowledge in that respect constituted a confidential communication which the statute prohibited him to reveal. The confidential nature of the communication could not be waived by any one except the father himself. The privilege of the statute would not amount to very much if the physician were permitted to testify in this indirect manner to facts concerning which he could not give direct testimony. The testimony clearly was not admissible. A waiver by the insured of the privilege so far as confidential communications between himself and another physician were concerned did not extend to confidential communications between his father and his father's physicians.

Society Proceedings

SOUTHERN SURGICAL ASSOCIATION

Thirty-Second Annual Meeting, held in New Orleans, Dec. 16-18, 1919

The President, DR. JAMES E. THOMPSON, Galveston, Texas, in the Chair

Injection of the Gasserian Ganglion for Neuralgia and Other Conditions

DR. CARROLL W. ALLEN, New Orleans: The proper execution of the technic of this injection demands a thorough knowledge of the anatomy of the parts involved, and of the effects of injected alcohol on these parts. The method most commonly used and the one practiced by me almost exclusively is the Haertel route. It has been found that chromium sulphate exerts a curative influence on the keratitis which sometimes follows these injections. Accordingly, I have in all recent cases been giving a 4-grain tablet of this salt, three times daily, as a prophylactic, advising its use for about one month. In my last twelve cases there has been no evidence of eye inflammation. From my experience, I am convinced that when the value of these injections for these conditions are recognized they will be used extensively.

Gunshot Wounds of Brain with Retained Missiles

DR. CHARLES BAGLEY, JR., Baltimore: During the spring and summer of 1918, 175 cases of gunshot wounds of the skull and brain were studied at General Hospital No. 2, Baltimore. Removal of the foreign bodies was undertaken because of the presence or probability of infection. I am of the opinion that because of the likelihood of metallic foreign bodies of average size giving trouble even several months after the injury, they should be removed, if their removal does not offer too great difficulties. However, a metallic foreign body may remain encapsulated in the brain substance without giving trouble.

Spermatocoeles and Hydroceles Containing Spermatozoa

DR. RANDOLPH WINSLOW, Baltimore: The occurrence of six cases of hydrocele containing spermatozoa, and of one of true spermatocoele associated with a hydrocele in the course of a few months, has directed my attention to this condition. In the cases of which I have notes, no mention is made of an injury, except in one instance. I think it probable that in some cases, at least, true spermatocoeles rupture into hydroceles and in that manner permit the ingress of spermatozoa into the sac of the tunica vaginalis. In one case there was a hydrocele with clear contents; and contiguous to but not communicating with it was another cyst containing a milky looking fluid, which showed spermatozoa when examined microscopically. This cyst might have ruptured into the hydrocele if it had remained unoperated on. The treatment of true spermatocoele is usually excision, while that of the hydrocele containing spermatozoa is similar to that of ordinary hydroceles, namely, excision of the tunica vaginalis, or suturing the tunica behind the testicle, or Andrew's bottle operation, etc., and the results appear to be equally as good as in cases of uncomplicated hydroceles.

Hypodermoclysis

DR. WILLARD BARTLETT, St. Louis: When continuous hypodermoclysis is used, the visible dropper and screw clamp are added. An attempt is made to get gravity pressure by placing the container directly above the patient. As to the fluid employed, Dr. McKittrick proposed that we use plain, freshly distilled water. In view of the large amounts of fluid instilled, and the harmful effects which occasionally follow the absorption of abnormal amounts of sodium chlorid, we do not countenance its use, especially in patients already weakened by disease or surgical trauma. The water is heated to between 100 and 110 F. and is then poured into the warm container. The injection is made at a point near the outer border of the pectoral muscles, midway between the nipple and the head of the humerus. By this method, the fluid extends directly into the subcutaneous tissue of both the axilla and the breast. Absorption is almost twice as fast as

it is when the injection is under the breast alone. Only the one side is used at a time, regardless of the amount of fluid to be infused. Usually from 800 to 1,200 c.c. are given during one injection, though a much larger amount can be given if it is allowed to run in slowly. The giving of hypodermoclysis is easily accomplished without pain or distress in most patients not under the influence of a narcotic. The procedure has completely supplanted the rectal administration in my service, and when intelligently applied, seems not to have unduly disturbed the patient, has never been attended by an accident, and has given the greatest satisfaction.

Pseudomyxoma Peritonei

DR. M. H. BIGGS, Rutherfordton, N. C.: This condition is much more frequent than is generally recognized. It is caused by cellular implantation. It is histologically benign, but may be clinically malignant. If it is considered to be a form of cancer, it must be assumed that pseudomucin inhibits its destructive power. It may originate in the ovary or the intestinal tract, ovarian origin being by far the most frequent. If it is appendical in origin, the appendix has been the seat of chronic inflammation. Early invasion of the peritoneum is characterized by a pebbly appearance. In early cases the condition will sometimes be cured, and at any stage it may be inhibited, by operation.

Pseudomyxoma Peritonei in Male Subjects

DR. M. G. SEELIG, St. Louis: The characterizing feature of the disease is the accumulation of a colloid exudate in the peritoneal cavity, varying in consistency from a syrup to solid colloid masses. In some instances there is a progressive cachexia leading to death; in others the disease runs a benign course with perfect recovery after suitable operative procedure and often doubtlessly without operation. In some cases the colloid material is confined in loculi whose walls are made up of a connective tissue new growth so firm and abundant that it fuses all the viscera into a solid mass, molded, as it were, into the peritoneal cavity. The appendix is the sole responsible agent for the disease as we encounter it in the male. Treatment consists in removing the primary focus of disease—the appendix—and scooping out that portion of the exudate which can be reached conveniently and with safety, without any attempt to clear the abdominal cavity of its entire pseudomucinous contents.

A Warning Against Promiscuous Uterine Curettage

DR. J. WESLEY BOVÉE, Washington, D. C.: It is well to point out the many dangers incident to uterine curettage. Not infrequently is a pregnancy in its first month thus scraped from the uterus and perhaps never recognized. Certainly humiliation has often come to the operator by discovering during curettage that an unsuspected pregnancy has been interrupted. Very often pregnancy has unnecessarily been ended by curettage for incomplete abortion. The literature teems with reports of cases of perforation of the uterus by the curet with or without dangerous sequels and even death. The cervical canal is so constantly infected that it does not seem strange that infection may be carried from it into the uterine cavity by the curet, sound or dilator. Again, it is shown by Curtis that infection of the endometrium is nearly always associated with similar infection of the tubes and most often gonorrheal. Curettement under such conditions is strongly contraindicated. The dangers from curetting are ever present. If chronic endometritis as a clinical entity is to be ruled out, one potent indication for curettage in the past will be removed.

Operative Treatment of Pelvic Inflammation

DR. CHARLES R. ROBBINS, Richmond, Va.: Pelvic inflammation is most frequently due to one of two causes: gonorrhea or infections following abortion or labor at term. Operation in gonorrheal cases may be performed with comparative safety at any stage, but radical operation in the septicemic group, in the acute stage, is attended by a high mortality and should not be done. Delay in operation on the septicemic group is an advantage, is less dangerous, and often results in symptomatic or absolute cure. The best method of treatment is that usually known as the Fowler-Ochsner-

Murphy treatment. The details of operation on which emphasis is laid are the complete removal of the tube, excising also the uterine portion, and the attachment of the broad ligament to the horn of the uterus, thereby elevating the ovary away from pressure and adhesions and the temporary suspension of the uterus.

Stone in the Kidney

DR. CHARLES H. MAYO, Rochester, Minn.: Stones form in the cortex, in the calices, and in the pelvis of the kidney. The kidney is constantly eliminating living bacteria, so that it is always exposed to infection, and usually shows no results from it except gross lesions of rare occurrence. Stone formation may proceed with exceeding slowness, and without pain or other symptoms until marked destruction of the kidney occurs, mixed infection develops, or until the stone assumes great size or becomes loosened and moves into the ureter. If the stone originates in the cortex of the kidney, its growth will be slow; but if it originates in the calices or pelvis, growth may be much more rapid because of the ease with which its chemical material is secured.

Results of Operations for the Removal of Stones from the Ureter

DR. E. S. JUDD, Rochester, Minn.: Stones in the ureter may pass voluntarily into the bladder. In my experience 12 per cent. of a group of 400 persons have admitted the passing of stones. Stones may be lodged in the ureter and produce no symptoms, and again they may produce the classic syndrome of ureteral calculus. There are two methods of treatment: the nonoperative and the operative. The first method consists in the dislodging of the stone by a ureteral catheter or small sound. The kidney should not be removed unless extensively infected, as it may recover its function. Conservative methods are justified in any case of chronic kidney infection, while radical methods must be employed in acute, severe infections. Nephrectomy is the operation of choice. Dr. Braasch has removed ureteral stones in about 126 cases by nonoperative methods. During the same period, 400 patients were operated on; about half the patients require operation to rid them of stone. Two deaths occurred in the series of 400 cases, only one of which was directly due to the operation.

Uretero-Ureteral Anastomosis

DR. REUBEN PETERSON, Ann Arbor, Mich.: Ureteral Anastomosis is a perfectly feasible procedure. Not only can the duct be made patent with little or no stricture, but a functioning kidney and ureter can result. In skilled hands, the primary mortality should be very small. The invagination methods are preferable to the transverse end-to-end method, since they are followed by fewer cases of leakage. The end-in-end method of anastomosis is the operation of choice. It is extremely simple, and sacrifices the minimum amount of the ureter.

Sarcoma of Stomach

DR. WILLIAM D. HAGGARD, Nashville, Tenn.: Primary gastric sarcoma is one of the rarest surgical diseases. A certain diagnosis of sarcoma of the stomach before operation is practically impossible. Only an operative diagnosis is possible. Hemorrhage from the stomach and blood in the stools are a frequent occurrence, especially in the round cell variety, although in sarcoma it is not so frequent as in cancer. Early exploration should be invoked.

Gastro-Enterostomy Following Rammstedt Operation Which Failed to Relieve the Obstruction

DR. FRANK D. SMYTHE, Memphis, Tenn.: Posterior gastro-enterostomy should be performed as a last resort in cases in which a Rammstedt operation has failed to relieve the obstruction. An otherwise hopeless case may be saved thereby, as in my case. The second operation was done seventy-six hours after the first.

Ileostomy for Postoperative Obstruction Following Appendectomy

DR. EDWARD P. RICHARDSON, Boston: I have to report seven cases of obstruction occurring during convalescence from

appendicitis. In five of these, ileostomy was done for obstruction apparently mechanical in nature. Four of these patients were children. Recovery with spontaneous closure of the fistula occurred, the patients remaining well for from one to eight years. These results suggest that ileostomy is a more favorable method of treatment in obstruction by recent adhesions than in other types of obstruction. Good results depend on the operation being undertaken early, and it is far better to operate unnecessarily occasionally than to postpone operation until the later stages of obstruction have developed.

Surgical Drainage from a Biologic Standpoint

DR. J. SHELTON HORSLEY, Richmond, Va.: Drainage from the abdominal cavity is practically always uphill, and yet it is successful because the drainage material not only relieves the pressure, but also provokes the outpouring of large quantities of lymph in an effort to extrude the drainage material, and this serum carries along with it products of bacterial infection that might otherwise be absorbed. In solid soft tissue, as in the thigh, the lymph supply is not so abundant, and consequently gravity drainage must be used. In the abdomen, the supply of lymph is so abundant and its pouring out so constant along the drainage tract it makes little difference whether the drainage tube is pointed up or down, so long as it is of sufficient size and of the proper kind of material to provoke the outpouring of serum. Drainage should be instituted after every radical operation for cancer of the breast or neck, as it tends to prevent the absorption of cancer cells that may be left in the wound. Drainage of infected epithelial lined hollow viscera carries off the inflammatory products, affords physiologic rest, and also produces a reversal of the circulation of the local lymphatics that will prevent the absorption of much of the septic products. Drainage material should be selected with a view to inducing a reversed flow of lymph to carry away the liquid products of the wound, and also with a view to injuring the wound as little as possible. Ideal drainage material has not been found, but empirically combinations of gauze and rubber tissue have been worked out that are fairly satisfactory.

Carrel-Dakin Treatment of Infected Wounds

DR. E. DUNBAR NEWELL, Chattanooga, Tenn.: It was almost universally observed in the hospitals of the American Expeditionary Forces that patients whose infected wounds had been properly treated by the Carrel-Dakin method suffered less pain, had less systemic infection, were more alert and cheerful, had a more rapid convalescence, and the wounds closed far earlier and with less deformity and less morbidity than in those patients whose infected wounds were treated by other methods.

Results and Feasibility of Treating Lymphangiomas with Injections of Boiling Water

DR. FRANCIS REDER, St. Louis: So far eight patients have been injected with boiling water. The reaction following the injection seemed unusually severe when compared with the reaction following the injection of a hemangioma. For twenty-four hours the patient gave evidence of feeling sick, and usually registered a temperature of 100 or 101 F. with a pulse from 100 to 110. When the reaction had passed off, which was generally after the third day, the feeling of euphoria returned. The increase in the size of the tumor after the injection, although considerable, bore a minor ratio to the increase seen in hemangiomas after injection. Inflammatory processes seemed active and prolonged, the skin giving evidence of the severity by a marked reddish discoloration. Retrogression seemed very slow. It required from four to six months to show that the tumor had decreased in size. In the case of a baby with the left foot about four times its normal size, it required two years for the foot to attain the size to be fitted with a shoe. Subsequent injections are almost impossible to be given, if the initial injection has been a thorough one. The tumor mass is so hard that no hot water can be forced into it. All of the eight patients injected with boiling water have been benefited, but in none has the tumor entirely disappeared.

Some Plastic Operations on the Rectum

DR. HARVEY B. STONE, Baltimore: In certain special types of stricture of the rectum, an application of the principle of the Heineke-Mikulicz pyloroplasty is helpful. These strictures are of the diaphragm type; that is, firm, with small lumen, but narrow and annular in their involvement of the long axis of the bowel. In tubular strictures of the rectum, occurring in the lower 4 inches of the bowel in multiparous women, the utilization of part of the voluminous vaginal mucosa as a transplant into the rectum has been tried. This has been done only when long continued dilatations have failed to give relief, and when the Wassermann test has been for a long time negative. The advantages of this operation are direct closure of the urethral orifice, the complete removal of the fistulous area of the rectum, the interposition of perineal structures between rectum and urethra, and the temporary diversion of the urine. It has proved very successful in practice.

Autogenous Bone Grafting for Repair in Fractures of Long Bones

DR. FRANK MARTIN, Baltimore: The chief factors for successful bone grafting are perfect aseptic technic; avoidance of mechanical injury or trauma to the graft; scrupulous avoidance of traumatizing tissues; definite and firm fixation of the graft, and the allowing of a long interval to elapse after complete healing of the wound. Grafts will not remain viable when there is infection. There should be perfect hemostasis.

Oxycephaly

DR. STEPHEN H. WATTS, Charlottesville, Va.: It is only in recent years that operative measures have been undertaken with the object of combating the symptoms of increased intracranial pressure, especially the threatened blindness. Since most observers think that this increased pressure is due to the disproportionate growth of the brain and skull, decompression seems to be the operation of choice; moreover, it has the advantage of simplicity and relative safety. It should be done early, for in cases with irreparable optic atrophy and no other pressure symptoms, operation is not indicated. The results of this operation in the small number of cases in which it has been done are distinctly encouraging, in spite of the fact that the optic atrophy was rather advanced in most instances. The patient on whom I did a bilateral subtemporal decompression was seen about two years after this operation. His general condition was much better, and he seemed to see better, as he stumbled much less in walking. He could count fingers at 3 feet, which he could not do before operation. Examination of the eye grounds, however, detected practically no change, there being a marked optic atrophy in both eyes. An interesting feature of this case is that at operation the bulging of the brain was so marked that the temporal fascia could not be at all approximated on either side; therefore the defects were covered by transplanted patches of fascia lata. Another point of interest is the ossification of the tissues over the region of the decompression, this bone showing the same digital impressions as the rest of the skull.

An Efficient Treatment for Carbuncle

DR. A. C. SCOTT, Temple, Texas: By strong traction the mass is lifted out of its bed while the cautery sweeps back and forth between it and the cellular tissue below or skims along the fascia covering the muscle beneath or penetrating the muscle, if necessary, until the entire mass is free. If any vessels spurt freely or fail to close when the cautery is held in contact with them a few seconds, they should be ligated. Any doubtful places beneath the remaining skin margins should be explored by the cautery tip. If the emission of steam is noted, the cautery should be applied until the cavity is apparently dry. Such a wound is now sterile and may be handled as any sterile burn. As soon as all burned tissue has been cleared away, perforated skin grafts sufficient to cover the granular surface soon complete the cure. The period of convalescence appears to be 50 per cent. less than by the old methods of treatment.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

American Journal of Diseases of Children, Chicago

January, 1920, 19, No. 1

- *Study of Achondroplasia. T. F. Wheeldon, Richmond, Va.—p. 1.
- *Food Value of Milk of Water Buffalo. W. W. Cadbury, Canton, China.—p. 38.
- *Dextrose Tolerance in Atrophic Infants. P. M. Mattill, K. M. Mayer, and L. W. Sauer, Chicago.—p. 42.
- *Case of Hypersensitiveness to Cow's Milk. E. A. Park, Baltimore.—p. 46.
- Anomaly of Diaphragm, with Herniation into Thorax of Certain Viscera Resulting in Gastric and Intestinal Obstruction. L. R. DeBuys, New Orleans.—p. 55.

Achondroplasia.—Wheeldon reviews the literature and reports six cases. Two show a new symptom, a wedge-shaped vertebra, which falls in the group of symptoms of infolding, and which, Wheeldon says, fortifies the belief that achondroplasia is produced by the smallness of the amnion.

Milk of Water Buffalo.—Cadbury shows that the milk of the water buffalo is a valuable dairy product and contains on an average 12.6 per cent. of fat. This milk can easily be modified for infant's use, as is shown by a table of formulas.

Dextrose Tolerance.—The dextrose (glucose) tolerance of the approximately normal infant, as determined by the Woodyatt method, is very likely identical with that of the normal adult, which is 0.8 to 0.9 gm. per kilogram per hour. But the tolerance of atrophic infants for dextrose is considerably greater: it varied in the authors' seven cases from 1.4 or 1.5 gm. to 1.8 gm. per kilogram per hour.

Hypersensitiveness to Cow's Milk.—Park reports the existence of hypersensitiveness to cow's milk in an infant 6 weeks old who had never been known to receive cow's milk previously, so that it seems necessary to regard the condition as prenatal in origin. The possibility that the hypersensitiveness was derived passively from the mother was excluded by its duration. In the absence of evidence that the peculiarity was acquired, it must be regarded as having been inherent in the germ plasm. Attempts at desensitization were successful.

American Journal of Insanity, Baltimore

- *Problem of Nutrition and a Satisfactory Method of Feeding in High Intestinal Fistulas. M. M. Peet, Ann Arbor, Mich.—p. 839.
- Later Stages of So-Called War Nephritis. T. Howard and A. F. Robertson, U. S. Army.—p. 845.
- Lethargic Encephalitis in the A. E. F. A. Skversky, New York.—p. 849.
- Significance of Certain Pulmonary Lesions in Relation to Etiology of Influenza. E. W. Goodpasture, Boston.—p. 863.
- Roentgenologic Determination of Pulmonary Tuberculosis. F. E. Diemer and I. H. Cramer, Portland, Ore.—p. 871.

Rupture of Aortic Aneurysm.—In Herrick's case the rupture was less than 1 cm. from the superior vena cava. The opening was 1.5 cm. in diameter. A typical syphilitic aortitis was present. Herrick discusses the clinical history and reviews the literature.

Postural Changes in Blood Pressures.—Sewall analyzes much material to demonstrate anew the clinical importance of tests to determine the quantitative range as contrasted with the qualitative perversion of physiologic functions. It is suggested that estimations should be made under different conditions of the velocity of the blood current, as represented by the product obtained in multiplying the pulse pressure by the pulse rate. Attention is called to the great frequency with which, in persons suffering from weakness of the circulation, the pulse sounds revealed by the auscultatory method are enfeebled or absent.

Lungs and Blood in Effort Syndrome.—Neither the number of cases found nor the degree of decrease of vital capacity present in the series studied by Adams and Sturgis is sufficient to indicate that the tendency to dyspnea in these patients is in any way dependent on a diminished vital capacity of the lungs. Tests of general muscular strength showed no relation between the muscular development and the vital capacity of the lungs. Observations were made in fifty-four cases, and from the carbon dioxid chemically bound as bicarbonate was found to fall within normal limits in all instances. Since, therefore, the carbon dioxid combining capacity of the blood is normal, there is no indication that a decrease in the buffer salts of the blood is a factor in the production of dyspnea in patients with "irritable heart."

Effort Syndrome with Measured Work.—A study was undertaken by Mabon of the changes in pulse rate and blood pressure taking place in fifty patients with "effort syndrome" after the hardest exercise which they could be induced to perform. These were, for the most part, patients with symptoms of many years' duration. The amount of work which they could do before becoming fatigued was much less than was done by normal controls. The pulse rate at rest was higher than in the normals, but the rise after exercise and the time for return of the pulse rate to its resting value were not definitely abnormal. No "delayed rise" of blood pressure, suggesting myocardial inefficiency, was observed. The amount of work which the subjects were able to perform usually corresponded closely to their physical strength, as determined by tests of the skeletal muscles, and this, Mabon says, indicates that lack of development of the skeletal muscular system is a factor to be considered in the cause of the fatigue following slight exertion in certain types of cases of "effort syndrome."

Arm in Blood Pressure Measurements.—Tests were made by Kahn to note the effect of raising the arm on auscultatory blood pressure readings. The normal effect is a progressive fall of the systolic and diastolic pressure readings as the arm is raised upward; the amount of fall increases with the elevation. Therefore, blood pressure readings should be obtained with the patient's arm at the side of his chest, as the normal reading varies considerably with the arm in different positions. This holds good for the seated, the standing and the recumbent postures.

Polyglandular Disease in Acromegaly.—From an analysis made by Howard of six cases it is evident that a secondary hyperpituitarism may result from a greatly or rapidly increasing intracranial pressure. The determination of a decrease in the sugar tolerance in the presence of other symptoms of disturbance of pituitary function justifies a diagnosis of increased activity of the pars intermedia. The epinephrin conjunctival test may be of positive value in certain cases of dyspituitarism in demonstrating a hypofunction of the chromaffin system. The subcutaneous epinephrin test was only of doubtful value in both normal and pathologic cases. Both the conjunctival and subcutaneous pituitary extract tests were too equivocal to be depended on for studying the functional activity of the hypophysis. The internal administration of the pituitary extract of either the whole gland or the anterior or the posterior lobes appears to exert no definite influence on the symptomatology of the disease.

Nutrition and Feeding in Intestinal Fistulas.—The problem of nutrition in high intestinal fistulas is solved by Peet by the enteric administration of foodstuffs through a small, soft catheter, inserted by way of the fistula into the efferent loop. By this method sufficient calories are utilized to maintain a good, physical condition and to build up an emaciated patient, so that he can withstand necessary operative treatment.

Lymphosarcoma of Mesentery.—The case presented by Bigelow and Forman adds one to the few cases of mesenteric sarcoma on record and the long list of sarcomas in other regions where the onset of the symptoms and the development of a tumor have followed a definite history of trauma. The patient suffered from abdominal "cramps" for several weeks before the "lump" was noticed. The case conforms to the established picture of a regional lymphosarcoma. The size of the mesenteric mass, as compared with the involved retroperitoneal nodes, leaves little doubt that the tumor arose in the mesentery.

Recurrent Nephrolithiasis.—Thorough flushing of the urinary channels through drinking freely of water, preferably of distilled water, Lamson says, may help in the dislodgment and removal of any possible nucleus of future stones. This treatment must be continued for a considerable period even after the urine has completely cleared up. Faulty or incomplete surgery, by leaving in the pelvis fragments of stones, may contribute toward a recurrence of nephrolithiasis.

Hour-Glass Bladder.—Caulk emphasizes the importance of free mobilization of the bladder before resection; the value of ureter catheter drainage in bladder resection; the need of complete removal of such transverse partitions and not temporizing with mere slit operations; the importance of vesical spasm in the neighborhood of inflammatory areas, and the protective value to a kidney of removing causes of vesical spasm in the presence of a patent ureteral vesical valve.

Treatment of Bone Cavities.—When the removal of sufficient portions of the wall of the cavity to allow the soft parts to fall in and fill it up is impracticable, as in certain tunnels and cavities near joints, some form of plugging is

indicated. Of the many materials used as plugs Martin favors the free fat transplants.

Résumé of Neurologic and Psychiatric Observations in a Hospital Center in France. J. W. Stephenson, New York.—p. 61.

Lethargic Encephalitis.—The case reported by Calhoun belongs to the new epidemic encephalitis group. The pathology is an acute infiltrative encephalomyelitis, the most marked changes occurring about the blood vessels of the thalamus, the cranial nerve nuclei, the floor of the fourth ventricle and in the white substance of the spinal cord.

Gunshot Wounds of Head.—The conditions in which Frazier and Ingham believe operation for cranial defects is indicated are: 1. For cosmetic reasons, especially when the defect is in the frontal region below the hair line. 2. In certain selected cases of epilepsy. 3. In the presence of a large defect where the brain is exposed to trauma. 4. When the patient is apprehensive, because of the defect and he dreads the possibility of a direct blow on the uncovered cortex. 5. In a few cases where the symptoms are wholly subjective an operation is advisable in the hope that, combined with the influence of suggestion, the neurosis will be relieved. Under these indications the authors have operated in fifty-nine out of 153 cases of cranial defects.

Studies on Anterior Horn Cells.—Cell counts were made by Taft on the anterior horns of the spinal cord in twenty-eight cases. Three of these were cases following amputation of an extremity. The twenty-five additional cases were said not to have had signs of a cord lesions. Variations in the counts between the two sides in the amputated cases was not more than two or three cells in the final average. In two of these, the greater number was on the side corresponding to the amputation. Variations in the counts between the two sides in the cases without amputation was at times greater than with amputation. In the sections where identification was made of the right and left sides, there appears no uniform difference between the two corresponding counts.

Lymphocyte in Resistance to Transplanted Cancer.—Murphy and Nakahara found that mice immunized against cancer by means of an injection of defibrinated blood show in the germinal centers of the lymphoid organs a marked increase in the numbers of mitotic figures. The increase becomes evident forty-eight hours after the injection in the majority of instances, and reaches its climax at about the fifth day. After this time it subsides, returning to the normal rate about the tenth day. These immunized animals, when inoculated with a cancer graft ten days after the injection, show a second stimulation of the lymphoid centers similar to the first but more intense in character. This increase in the number of mitotic figures becomes evident as early as twenty-four hours after the cancer inoculation and persists in a marked degree for a week, after which there is a gradual return to the normal rate. The lymphocytes of the circulating blood during the establishment of the immunity show frequent examples of amitotic division, and many examples of irregular and lobulated nuclei. These changes suggest intensified functional activity. Cellular reaction in the subcutaneous tissues of immunized animals is present only in the region infiltrated by the injected cells. This fact becomes conspicuous when the immunizing injection is given intraperitoneally, in which case no cellular accumulations are noted in the loose connective tissues. No constant cellular changes were noted in the bone marrow, thymus or thyroid gland, liver or kidney of the treated animals.

Bacillus Dysenteriae Shiga.—Olitsky and Kligler have separated an exotoxin and an endotoxin from cultures of the Shiga dysentery bacillus. The two toxins are physically and biologically distinct. The exotoxin is relatively heat labile, arises in the early period of growth, and yields an antiexotoxic immune serum. The endotoxin, on the other hand, is heat stable, is formed in the later period of growth, and is not neutralized by the antiexotoxic serum. The exotoxin exhibits a specific affinity for the central nervous organs in the rabbit, giving rise to a characteristic lesion—mainly, hemorrhages, necroses and possibly a perivascular infiltration in the gray matter of the upper spinal cord and medulla. The endotoxin exerts a typical action on the intestinal tract, producing edema, hemorrhages, necroses and ulcerations, especially in the large intestine. A potent anti-dysenteric serum should contain antibodies against the exotoxin as well as the endotoxin. That such a serum can be produced in horses has been demonstrated experimentally.

Dairy Infection with Epidemic Streptococcus.—A streptococcus epidemic of moderate extent and severity was characterized by clinical symptoms different from the usual septic

sore throat, though the organism found was culturally *Streptococcus epidemicus*. The infection was traced to the milk from a single quarter of the udder of a cow in a dairy of 112 cows producing an otherwise excellent grade of raw milk. A number of the milkers on the dairy farm were found infected. It was impossible to trace the infection of the cow's udder to any one of the milkers, though such an infection seems probable since the streptococcus isolated from the cow was in every respect like streptococci isolated from patients and milkers, and different from those usually found in normal cows or cows with garget. Certain recommendations are made to safeguard producers of raw milk against the occurrence of such epidemics.

Standardization of Bacterial Suspensions.—The opacity of a bacterial suspension is measured by the length of the column of the suspension required to cause the disappearance of a wire loop. By a simple formula the measured opacity is translated into terms of the concentration of bacteria per cubic centimeter, and so made comparable with that of other suspensions of the same organism. An instrument for measuring the opacity of bacterial suspensions is described in detail.

- *Complement Fixation in Diagnosis of Tuberculosis. W. H. Moursund, Ft. Sam Houston, Texas.—p. 85.

Nonlactose Fermenters in Feces in Influenza.—Bacteriologic examinations of the feces of thirty-two patients with influenza showed the presence of *B. typhosus* in three, and of enteritidis-like organisms in seventeen others. Examination in control cases (one case of typhoid and one of mumps, two cases of measles, three cases of tonsillitis, several cases of lobar pneumonia and several surgical cases) yielded *B. typhosus* in the case of typhoid, but no enteritidis-like organisms in any of the other cases. There seemed to be no correlation between the nature of the stools and the presence of these organisms. They were found in both diarrheal and constipated stools, in mild and severe cases of influenza. The authors point out that if these organisms have no clinical significance in these cases, it would seem to raise the question as to the value of much of the published work on epidemics of food poisoning, supposedly due to enteritidis-like organisms where the mere presence in feces, coupled with more or less vague clinical pictures quite similar to many cases of influenza, have been assumed to prove the enteritidis-like organisms as being the causative factor.

Hemolytic Streptococci in the Throat.—The throats of 300 patients were examined by Otteraaen. He says that hemolytic streptococci are frequent inhabitants of the throats of normal individuals and of persons suffering from acute infectious diseases. These streptococci are not virulent so far as indicated by the results of animal inoculations and phagocytoses experiments. Otteraaen says that the enrichment method should be used in preference to the surface plate method in examinations for streptococci.

Complement Fixation in Diagnosis of Tuberculosis.—The complement fixation test for tuberculosis, as described in Moursund's paper, is of no value as a diagnostic or prognostic aid. The complement fixation test for tuberculosis with alcoholic extract of tubercle bacilli as antigen is not specific.

Not all complement fixation tests with bacterial antigens are specific. A large percentage of serums giving a positive Wassermann reaction give fixation with tubercle and gonococcus antigens. A certain number of individuals not infected with tuberculosis or gonorrhea will give positive fixation tests with one or both of the corresponding antigens.

- *Preformed Ammonia in Cerebrospinal Fluid. P. F. Morse and E. S. Crump, Detroit.—p. 185.

Glycogen and Pancreatic Diabetes.—Glycogen is a stabilizing colloid in the cell and as such prevents the breaking of the emulsion or fatty degeneration by its resistance to acids, salts, etc. Glycogen is hydrolyzed by acids, and when hydrolyzed, there is left a protein-fat emulsion that is but poorly resistant against acids. In diabetes, Ervin says, no glycogen is formed, the fat is only slightly emulsified, permitting a high concentration of the fats or soaps to reach the cell and a consequent limited oxidation with the production of the acetone bodies. The equilibrium of glycogen with glucose is shifted toward the glucose side by the presence of the hydrogen ion; hence the high blood sugars in fevers, mercury and phosphorus poisoning and nephritis.

Pathology of Influenzal Pneumonia.—The pneumococcus and hemolytic streptococcus were the most frequent secondary invaders found in the lungs at necropsy in the pneumonias at Camp Sherman. Pfeiffer's bacillus was found in only 4 per cent. of the cases. Walker claims that interstitial and lobular bronchopneumonia cannot be regarded as typical lesions resulting from the invasion by the hemolytic streptococcus. The pneumococcus was found to be the only invader just as frequently as the hemolytic streptococcus in these types of pneumonias. In fact, it is doubtful whether the type of organism isolated from pulmonary tissue in pneumonia is of any great value in determining the type of pneumonia present, for the type of organism concerned and the type of lesion in the lung are decidedly variable at different times even at the same station. Influenzal pneumonia is primarily an acute, hemorrhagic lesion, interstitial, nodular, or massive in extent, arising from a pulmonary capillary phlebitis with disseminated capillary necrosis due to some toxic agent, and resulting in a secondary purulent pneumonia with healing by organization. The organism or organisms predominately present in nose or throat in the individual in any particular section of the country is the organism most commonly found in cultures and tissue sections from the lungs of secondary pneumonias in that region. Empyema and pericarditis were frequent complications.

Preformed Ammonia in Cerebrospinal Fluid.—Morse and Crump present a method for the determination of excess preformed ammonia in the spinal fluid, which they have found to be great value for quickly determining the cause of coma. To an appropriate quantity (2 c.c.) of spinal fluid, an equal quantity of Nessler's reagent is added. In normal persons and in conditions not tending to acidosis or nitrogen retention, scarcely any brown color develops. A cloudy greenish gray precipitate gradually forms and the fluid turns a dirty pale green color. When there is acidosis or nitrogen retention from any cause, a deep brown color develops immediately, the depth of color depending on the amount of ammonia present in the spinal fluid. Only one precaution is necessary. The fluid must be free from contaminating bacteria. These form ammonia and give false readings. Sterile spinal fluids, well corked, give good reactions even when several days old. The reaction is read immediately (within thirty seconds). In general, cases of acidosis associated with infection, and terminal stages of meningitis, develop less color than cases of uremia with nitrogen retention.

Penetration of Dichlorethylsulphid.—The experiments recorded by Lillie and his associates lend strong support to the theory, that "mustard gas" penetrates the cell on account of its organosolubility, and within the cell undergoes hydrolysis, with the liberation of nascent hydrochloric acid, which exerts the destructive effect.

Effect of Pyretics and Antipyretics.—According to Burge, chloroform and ether lower temperature in so far as decreased oxidation is involved in this by decreasing catalase, the enzyme principally responsible for oxidation in the body. The fact that acetanilid, quinin and acetphenetidin have little or no effect in decreasing catalase suggests that their mode of action in lowering temperature is not due to a decrease in oxidation.

Drugs After Chlorin Gassing.—No evidence was obtained by Barbour favorable to the employment of subcutaneous injections of calcium lactate in edema of the lung. Calcium was tested in twenty-three, quinin in eight and atropin in four gassed dogs, without a single recovery.

Do Local Anesthetics Precipitate Proteins?—Sollmann's experiments show that most of the local anesthetics now available do not precipitate proteins, and none did so to a serious degree.

Roentgen-Ray Findings with Delineator in Cardiospasm.—Einhorn claims that this is the best method for studying

cases of cardiospasm. The delineator string, once swallowed by the patient, may remain in situ for any length of time, outlining permanently the course of the esophagus and reacting even to slight spastic conditions of the organ. In the normal esophagus the course of the string shows a straight line. In the spastic organ the course of the string is more or less tortuous, according to the degree of spasticity. The instrument casts a definite shadow on the fluoroscopic screen as well as on the plate. The patient, therefore, can be examined repeatedly during any period of time, and at the roentgenologist's leisure, without subjecting the patient to the inconvenience of repeated ingestions of contrast mixtures. If necessary, plates can be taken for records.

Convenient Method for Concentrating and Isolating Tubercle Bacilli.—Goeckel uses Rice's bromin and alkali reagent (Rice's solution No. 1: Bromin [pure], 1 ounce [30 gm.]; sodium bromid, 1 ounce [30 gm.]; distilled water, q. s. ad. 8 fluidounces [250 c.c.]; Rice's solution No. 2: Sodium hydroxid, 2½ ounces [70 gm.]; distilled water, q. s. ad. 8 fluidounces [250 c.c.]) not only on sputum, but likewise on tuberculous glands. To the sputum, caseous pus, or moderately cut or minced tissues add a few cubic centimeters of the sodium hydroxid solution (Rice's solution No. 2). Mix well and add Rice's bromin solution (No. 1) in successive small portions until a clear liquid is obtained. The use of heat is not necessary. The liquid is then diluted with distilled water to reduce the specific gravity and is centrifuged at high speed to precipitate the bacilli. These are then washed with two successive portions of distilled water, centrifuging to remove the alkali. The residue is mounted on a microscopic slide in the usual manner, using a trace of albumin to fix on the slide.

Recognition and Better Treatment for Mental and Nervous Injuries.—Donoghue emphasizes the need of calling to the assistance of the compensation boards men competent to diagnose and advise treatment in the psychoses, and through them to encourage the further standardization of this group of cases. The present method of handling them by exerting constant pressure from the insurance physician, insurance adjuster, or compensation commissioner, is not always a success. Nonacceptable work forced on a man tends to develop in him the reaction against work. Forcing a high class man to sweep a floor, may not be treatment; it may be the opposite. The difficulty of the administration of workmen's compensation by lay boards in this group of cases comes down to the unsurmountable fact that there is no specific treatment for hysteria. When a person presents himself he is coming more for relief than for monetary compensation.

Securing of Proper Medical Service for Injured Persons.—Trask outlines the work done by the U. S. Employee's Compensation Commission, its aims and objects, and particularly the requirements of a competent personnel. Physical restoration is accomplished through medical treatment in its broad sense. To be effective it must be competent and adequate. The question of satisfactory medical care for injury cases seems to resolve itself into ascertaining who are competent, well trained surgeons, with the necessary temperamental qualifications, and where they are located, and then placing the injury cases under their care. The experience of the commission has been that the whole problem depends on the selection of properly qualified surgeons who will conscientiously do whatever is possible toward the physical restoration of their patient.

Better Methods in Medical Service.—In Thompson's opinion, one thing essential to the betterment of the medical service, is the occasional meeting of the county and state medical societies and the presentation of papers that deal with the problems arising between the surgeons and the board. He urges doing away with the hospital contract system that too frequently renders poor service and overcharges the workman.

Hemoglobinuric Bilious Fever. C. G. Cumston, Geneva, Switzerland.—p. 944.

Causation and Treatment of Rickets.—Pritchard holds the view which is that practically all varieties of malnutrition occurring during infancy and early childhood tend to terminate in rickets, provided they are sufficiently severe or long enough continued. They should not, however, be regarded as evidence of rickets, unless they are actually accompanied by the typical changes in bone which are characteristic of the disease. The essential and central feature of rickets he believes is the want of calcification or mineralization of developing bone, and this in its turn is due to the existence of requirements for calcium which for the time being are more urgent than of developing bone. These urgent requirements are the necessity for neutralizing acid bodies in the blood; in other words, to neutralize or compensate an existing acidosis. In Pritchard's opinion all chronic conditions of malnutrition of whatever kind or from whatsoever cause finally terminate in an acidosis, and that all claims on alkaline bases arising in connection with the neutralization of this acidosis must be satisfied before those of developing bone are attended to. It is in the satisfaction of these claims for alkaline bases that the injury is done to growing bone.

Climacteric Hypertension.—In considering the treatment of climacteric hypertension Hopkins divides the condition into three stages: 1. The first or larval stage in which high blood pressure and nervousness are the chief symptoms. 2. The second stage, in which the pressure is higher and remains more constant and in which the gastric neurosis, cardiac or pressure symptoms, as headache, vertigo, etc., make their appearance. 3. The third stage comes later in life, i. e., in the sixth or seventh decade and represents what might be regarded as the early evidences of senility. The treatment for each stage is described in detail.

Shelley the Invalid.—An analysis of Shelley's writings bearing on his illness has convinced Moll that the poet was suffering from either gastric or duodenal ulcer.

Vaccinotherapy of Bacteriuria.—Nolf cites his experience with progressive intravenous vaccination in the treatment of these cases. His results have been very satisfactory.

Industrial Medicine and Surgery.—Little points out the needs of industrial medicine and surgery and suggests how these may be met by the medical profession. He would have a bureau headed by a practical business man who is also a surgeon, and which bureau will prepare, or have prepared pamphlets on the subject of health and the treatment of disease and injuries in clear, nontechnical, forcible language, which pamphlets should be sent to every chamber of commerce, manufacturers' association and trade body in the country. Letters should be sent to all the employers of the country, calling their attention to the necessity of health as a factor in industry and making suggestions concerning the proper organization of a health service in industrial plants. Little would have a roster of able men who can speak effectively on this subject before chambers of commerce, before manufacturers' associations and the leading trade bodies at their annual meetings, and also a roster of well qualified physicians and surgeons who are willing to enter the industrial field, provided suitable conditions and opportunities are open for them. This propaganda and education work should be carried into the medical schools and hospitals of the country in order that the regular medical course may provide training in industrial surgery.

Urine of White Races Living in Tropics.—The twenty-four hours' urine collected from a number of persons living in North Queensland and of different occupations was analyzed by Scott. The daily average volume was only 784 c.c. This volume was increased considerably in the cooler weather. The specific gravity was very much higher, while the freezing point did not differ very much from that found in Europe, thus the osmotic pressure was not very much higher. A striking difference was noticed in the quantity of sodium chlorid excreted in the urine, which was very low, and this may be accounted for by the large loss of water in the sweat which carries with it this salt. It is calculated that a man doing manual labor in the tropics must lose several grams of sodium chlorid per day through the skin, which would readily account for the deficiency in the urine. The total nitrogen showed a lower figure than that found in Europe, which cannot be accounted for by loss of nitrogen from the skin, since it is shown that this can only amount to 1 or 2 gm. per day under normal circumstances. These results differ from those obtained by other observers in other parts of the tropics.

Nerve Compression by First Dorsal Rib.—Ten cases of this type were seen by the authors in less than two years. Eight of these are described as belonging to the idiopathic group, while two were of traumatic origin. In all the ten cases, except one (and that was a very early one), objective sensory disturbances were present, and in all the nine cases, loss of protopathic sensibility was greater than the epicritic loss—a dissociation which Stopford has previously suggested as characteristic of nerve compression. Trophic and vasomotor phenomena were very constant, the most frequent being hypothermia, pallor or cyanosis, and trophic sores affecting the little and ring fingers and more rarely the inner border of the forearm. There does not appear to be any advantage in subdividing the cases into the three types—motor, sensory and trophic disturbances in the hand and forearm may be and sympathetic—according to which group of symptoms predominates, provided it is remembered that weakness of the hand, objective and subjective sensory manifestations,

the result of compression of the lower trunk by a first thoracic rib as well as by a supernumerary costal element.

Traumatic Myositis Ossificans.—Morley draws attention to the fact that gunshot wounds, and particularly shell wounds, which graze tangentially the smooth shaft of such a bone as the femur, may give rise to a growth of bone in the adjacent muscles precisely similar to the familiar myositis ossificans that follows a subcutaneous trauma. He also points out the value of this fact as evidence of the true nature of the process.

Paget's Disease of Nipple.—The nature of this disease is discussed at length by Handley, and he finally concludes that the probabilities all favor the view that the lymphatic obstruction which is the cause of Paget's eczema results from neoplastic and not from mere inflammatory obstruction of the lymphatics. Even if in rare cases it is possible that the eczema results from a block in the lymphatics of inflammatory origin, it is certain that this form of chronic inflammation of the ducts is a very dangerous condition which almost invariably leads to carcinoma. Paget acknowledged that in all cases in which he excised the eczematous nipple a carcinoma subsequently appeared in the breast. Early and complete removal of the breast is, therefore, demanded whatever the view adopted as to the order in time of the eczema and the carcinoma.

Operation for Exophthalmic Goiter.—In operating on the thyroid for exophthalmic goiter, Dunhill insists that only so much gland tissue should be removed as is necessary, but that this must be done even if more than one or even three operations should be performed. He is convinced that one cause of failure is leaving gland tissue which should have been removed cleanly, i. e., the posterior surface of the first lobe or portion of the isthmus, attached to the trachea. Small portions such as these always grow and function, and they cannot subsequently be dug out of their surrounding scar tissue without great difficulty. "What you remove, remove cleanly; what you leave, leave undisturbed. See that the portion left has always its blood supply intact. Failures are due to leaving too much gland behind." Dunhill prefers to operate under local anesthesia.

Repair of Bone.—Gallie and Robertson have made a complete review of the literature on the repair of bone, and performed a large number of experiments on animals in trying to arrive at a definite conclusion. They are of the opinion that periosteum is not osteogenetic, and should not be depended on under any circumstances to assist in the production of new bone. The presence or absence of the periosteum in autogenous bone transplants has no decided influence on the activity of the subperiosteal osteoblast, and is of no practical clinical importance. The periosteum is of great importance, however, from a clinical standpoint, because of its control of the circulation throughout living bone. Extensive stripping of the periosteum at operation will result in necrosis, which may cause delay in the union of aseptic fractures, and which will result in sequestration where sepsis is present. Disturbance of the circulation should be reduced to a minimum in all operations on bone. The method of new bone growth and other points of interest in connection with bone repair are discussed fully.

*Case of Hydatid Cyst. G. M. Butt.—p. 419.

*Case of Ectopic Gestation Which Burst into Rectum. E. B. Wolf.—p. 419.

Anticholera Inoculation.—Roy and Young report very favorably on the use of anticholera vaccines in the prevention of cholera. Even under the most unfavorable circumstances, as existed in one village, Roy succeeded in checking an extensive epidemic after all other measures had failed.

Ophitoxemia.—In Asana's case the treatment consisted in cleaning the bitten part, the application of antiseptic dressings, calcium chlorid in 10 gm. doses, every three hours, 0.33 gm. emetin hydrochlorid morning and evening hypodermically, and alum gargles for the mouth as often as possible. The treatment was continued for four days. On the eighth day the patient was well.

Abdominal Hydatid Cyst.—Butt removed an intra-abdominal hydatid cyst measuring 5½ inches in diameter from his patient. The cyst arose from the peritoneum.

Ectopia Cloacae. C. Walker.—p. 109.

Modified Wassermann Test.—In the method described by Wang the technic is simple, consisting in the mixing, in loopfuls, of an antigen with the suspected serum and the sensitized corpuscles, all at one and the same time. The blood required for the test is available from a prick and collected in small capillary tubes, such as those used for the Widal test. The examination need not be undertaken almost at once, as in Birt's test, but may be delayed to the third day, or perhaps even longer, after the sample has been taken. The test is said to be superior to the Wassermann.

Biochemistry of Pathogenic Anaerobes.—Experimental methods are described by Harris for carrying out a comparison of the biochemical reactions of two closely allied organisms. Details are given of the apparatus used for fermentation experiments, and of the methods for obtaining values for gas production, ammonia and amino-acid formation, production of volatile acids, and changes in hydrogen ion concentration and sugar content. A simple method is described for determining the degree of oxygen toleration of organisms for routine purposes; it is suggested that results should be expressed in the form of the "aerobic index," which is defined. A comparison is made of two anaerobes—*B. sporogenes* and the Reading bacillus—which, morphologically and in cultural reactions, are closely related. The

results are given of fermentations on five different mediums, and of determinations of the aerobic indices both of spores and young organisms on liquid and solid mediums. From the experimental results it is concluded that these two organisms are of the same race, but show small differences, possibly acquired. In their biochemical behavior toward the five mediums used, they are remarkably similar, but they show a somewhat striking difference in their powers of growing in the presence of oxygen. The use of methods, such as those described, for investigations of the biochemical properties of bacteria in general, is discussed, and a means is suggested for using these methods with aerobic organisms.

Paths of Spread of Bacterial Exotoxins.—The experiments recorded by Teale and Embleton show that although tetanus toxin ascends to the central nervous system by way of the axis cylinders of the nerves, it also to a very great extent passes up the nerves to the cord by way of the perineural lymphatics. Blocking of the latter paths greatly delays and in some cases completely prevents the occurrence of tetanus in the part corresponding to the nerve whose lymph path has been blocked. Although tetanus toxin passes rapidly from the blood vessels into the connective tissue spaces and thence to the thoracic duct, the toxin does not pass from the capillaries of the central nervous system to the tissues thereof. Tetanus toxin does not pass from the choroidal plexus to the cerebrospinal fluid. Although bacteria can pass through the posterior root ganglion to the cord, colloidal pigments and tetanus toxin are prevented from doing so. Iodin, although it prevents tetanus toxin from producing its characteristic effects when iodized toxin is inoculated subcutaneously or intravenously, does not affect the toxin when inoculated intracerebrally, it does not hinder the occurrence of the typical symptoms of cerebral tetanus, and there is no apparent diminution in its toxicity. Tetanus antitoxin does not pass to the central nervous system either by way of the blood vessels, axis cylinders, or neural lymphatic channels. It also cannot pass from the cerebrospinal fluid into the substance of the cord when inoculated intrathecally. The antitoxin simply acts by combining with the circulating toxin at the seat of production, and prevents it from reaching the central nervous system. The toxin already in this position is unaffected.

- *The Physiopathology of Jaundice. M. Brulé.—p. 709.
*System for Clinical Examination in Cases of Jaundice. F. Saint-Girons.—p. 713.
*Diagnosis of Jaundice. P. Améuille and R. Huguenin.—p. 717.
*Icterohemorrhagic Spirochetosis. P. Pagniez.—p. 720.

Physiopathology of Jaundice.—Brulé reiterates that besides hemolytic jaundice—which calls merely for iron and possibly splenectomy—discovery of dissociated retention of bile salts shows that the jaundice is due to insufficiency in liver functioning and not to mere obstruction of the biliary passages, from within or without. Recent research has confirmed that

infectious jaundice in the great majority of cases is the manifestation of disease in the liver, and hence operations, chologogues and measures to clear out and disinfect the biliary passages are useless when the stoppage of the course of the bile is in the liver itself. Treatment should aim to fortify and facilitate the task of the liver; ingestion of sugar, for example, promotes the glycogen function. Although therapeutic efforts in this line have been very imperfect to date, yet our increasing knowledge of the physiopathology of jaundice will certainly some day aid in corresponding improvement in its treatment.

Examination in Cases of Jaundice.—Saint-Girons devotes over four pages to the systematic outline of the questions to be asked in the clinical examination and the interpretation of the findings. Améuille and Huguenin give a similar systematic outline and technic for the laboratory tests to complete the clinical diagnosis.

Ictero-genous Spirochetosis.—Pagniez had only 15 per cent. typical forms in his 45 cases of ictero-genous spirochetosis in the Aisne district in the summer of 1917. The catarrhal jaundice type was encountered in 10 or 12 per cent. In 2 cases there was no jaundice with the spirochetosis, the meninges bearing the brunt of the attack. In 4 cases the meningeal syndrome preceded the jaundice. No really active antiserum seems to have been produced to date. Arsphenamin has given no results, and this medication, he says, has been completely abandoned. Lumbar puncture relieves the pain in the meningeal form but the danger in the graver cases is mostly from the kidneys. Hence abstention from nitrogenous food and repeated venesection are indispensable to enable the patient to resist the intoxication until kidney functioning becomes reestablished.

Neo-Arsphenamin in Treatment of Contracture and Spasms.

—Sicard relates that the by-effects of neo-arsphenamin on the nervous system can be utilized in direct treatment of certain nervous disturbances in both syphilitic and non-syphilitic. The arsenical inhibition may range from a simply sedative effect to abolition of all reflex action in the legs, depending on the dose and the way the drug is pushed; small injections by the vein every day or two are more potent than a weekly injection. The Achilles reflex has not returned during the fifteen months to date in some of his cases. This by-effect of arsphenamin may lead to the mistaken assumption of impending tabes unless the normal findings in the spinal fluid are taken into account, as also the electric responses, knee jerk and pupil reactions. A sedative influence on contractures and in chorea was evident after 4 or 5 gm. of neo-arsphenamin had been thus administered in the course of five or six weeks. This hitherto misinterpreted property of the drug can thus be utilized in many cases of pathologic nervous conditions, under control of the skin, nerve and azotemic reactions.

Bile by the Rectum in Treatment of Constipation.—Bensaude and Vincent have been amazed at the way in which beef gall (10 gm. extract of beef gall in a liter of water) started up peristalsis twelve hours after ingestion of a contrast meal. When the bile enema was given the opaque mass was in the ascending colon. It passed rapidly along and was expelled the fifth minute. This amount of the gall extract caused griping, but 5 gm. proved equally effectual without inducing colic. Various preparations of beef gall were tried, but 4 or 5 gm. of the powder form, that is, two teaspoonfuls in 250 gm. of tepid water, is the most convenient method. The gall does not seem to lose its efficacy in time, according to their several months of experience. They review the history

of the use of bile in medicine, beginning with the Egyptian papyrus thirteen centuries B. C. which among various prescriptions for enemas gives: "Beef gall $\frac{1}{3}$; cow's milk $\frac{1}{6}$. Usually cures in four days. A good remedy."

Dehydration of the Pancreas in Diabetic Coma.—Chauffard and Grigaut have long noted the extreme dehydration of the organs in diabetic coma, most pronounced in the pancreas. In a recent case, even the spinal fluid was thick and syrupy, and the coefficient of dehydration in the pancreas was 170 per thousand. Examination of the pancreas from diabetics and others succumbing to causes other than coma showed normal hydration of the pancreas.

Abdominal Reactions in Pneumococcus Septicemia.—In the case reported, the signs of grave general infection were accompanied by intense abdominal pain and extreme distention of the intestines with complete arrest of stools and flatus. There were no symptoms from the lungs, and an exploratory laparotomy showed no signs of peritonitis. The young woman died the seventh day. In another case the acute peritoneal reaction developed during convalescence from pneumonia. A suppurating joint lesion may have aided in the recovery, acting like a fixation abscess. Other cases are cited in which the course tended to suppuration, diffuse and fatal in some, or localized, with recovery. The relief was usually great as soon as a suppurating focus developed. *Pneumococcus pus* does not seem to be spontaneously resorbed and requires surgical measures.

Roentgenoscopy After Injection of Oxygen.—Ribadeau-Dumas expatiates on the remarkable precision with which the viscera can be inspected after intraperitoneal injection of a liter or two of oxygen. He changes the patient's attitude until the viscous shows best on the screen, and then roentgenographs it.

*Duodenal Ulcer with Ptosis. A. Durrieux and Parturier.—p. 966.

*Spontaneous Rupture of Aorta. Menetrier and Durand.—p. 968.

Diabetes and Exophthalmic Goiter.—Labbé describes the five cases he has encountered of this combination. The glycosuria in this thyroid diabetes seems to be more resistant and less dependent on the diet than in ordinary diabetes. In one of his cases the woman developed goiter at 20; glycosuria became installed at 50, and at 54 the symptoms of severe exophthalmic goiter developed and the diabetes became aggravated. Each time there was a hyperthyroid attack, with tachycardia, the sugar content of the urine and blood ran up high, scarcely modified by dietetic measures, but subsiding with the paroxysm of hyperthyroidism. He cites Manby, Lancereaux and others' reports of instances of diabetes in some members of a family and exophthalmic goiter in others. Diabetics with exophthalmic goiter seem to display an exceptional tendency to acidosis, probably from the derangement in nitrogen metabolism which is constant in exophthalmic goiter. He adds that the action of drugs also tends to individualize this form of diabetes; drugs like quinin and salicylate, which act on the goiter, modify likewise the glycosuria. In two of the cases described, treatment with iodine proved effectual; at the same time that the palpitations and tachycardia subsided, the glycosuria declined also. His five cases show the multiplicity of types which the diabetes may assume in these cases. A number of writers have called attention to the frequency of alimentary glycosuria in *basedowiens*. In the discussion that followed, Garnier related that when feeding animals suprarenal extract, a much higher degree of glycosuria was realized when thyroid extract was associated with it than when the suprarenal extract was given alone. Linossier commented on the exceptionally high alimentary glycosuria in some cases of exophthalmic goiter, but this does not occur in all. It is evident that in some cases the interaction of other glands may maintain a functional balance.

Parotitis in Meningitis.—The meningitis was declining in the two young men when the parotitis flared up.

Differential Diagnosis of Duodenal Ulcer.—The predominant symptom presented by the man of 32 was constantly

recurring intense dizziness, evidently from the upper digestive tract. The pains suggested duodenal ulcer, and this was confirmed by the constant painful point, at the middle of a line from the umbilicus to the tenth rib, not varying during inspiration or change of position. There was also a remote painful point at the left, between the two heads of the sternocleidomastoid muscle; Parturier has already called attention to this referred pain at this point as an aid in diagnosis of abdominal disease. Still further aid in the diagnosis was afforded by the elective action of belladonna in relieving the pain, while it was not modified by opium, which is so effectual with disease in the biliary apparatus. The stomach in this case sagged 8 cm. below the crest of the ilium.

Spontaneous Rupture of the Aorta.—The woman of 43 was syphilitic, and necropsy disclosed changes in the middle layer of the aorta which were of a different type from the specific arteritis hitherto described.

*Drop in Blood Pressure under Arsenic. A. Touraine.—p. 103.

*Practical Points. H. Gougerot and others.—p. 104.

Recent Progress in Skin Disease and Syphilis.—Gougerot reviews the achievements during the war in this line, mentioning Sicard's rachialbuminometer to measure the albumin in the cerebrospinal fluid. He says that arsenical treatment has modified syphilis so that it may enter the tertiary stage from the start; lesions of all three phases have been known to develop together of late. Syphilis represents a blending of immunity and sensitization, and there may be all forms of transitions between the complete, though retarded, secondary explosion and latent syphilis. This warns that the cure may be deceptive; several instances of supposed reinfection have proved to be merely delayed manifestations. "No new sign or method of treatment has been discovered, and the confidence in the Wassermann test is not so blind as formerly." Gougerot adds "We no longer count the cases of deaths and accidents from 914; among the more impressive was Leredde's patient dying with a purpuric syndrome after the twenty-third injection; Courtois-Suffit's dying in the physician's office after the eighth injection, and the soldier, dying from paraplegia (Gougerot)." He is inclined to ascribe the mishaps mainly to toxic action from the arsenic plus symptoms from the accelerated "tertiarization" of the disease under the drug. In conclusion he reiterates that a syphilitic may be contagious even when he has no lesions or only tertiary manifestations. Also that a syphilitic may reinoculate himself, and that inherited syphilis does not immunize against new contagion.

Infestation with Lice as a Symptom of Disease.—Jeanselme has repeatedly noticed that the perfectly healthy may escape phthiriasis even when sleeping with lice-infested persons. The lice colonize by preference on the diseased, and hence severe phthiriasis should impel a search for serious, possibly latent disease.

Serodiagnosis in Skin Diseases.—Joltrain expatiates on the facility and reliability of serodiagnostic measures applied to leprosy, mycosis and other skin diseases, although his experiences to date with skin cancers have been conflicting.

The Herxheimer Reaction.—Milian explains anew that the inflammatory reaction in the syphilitic tissues under the influence of specific treatment, known as the Herxheimer reaction, is the cause of jaundice, albuminuria and other symptoms which have been mistakenly ascribed to direct toxic action from the medication.

Syphilitic Meningitis.—Bloch argues that what we have been calling "neurorecurrences" and "meningorelapses" are in reality the paroxysmal flarings up of an inadequately

treated meningovascularitis. When the Wassermann reaction persists positive after vigorous treatment, the possibility of this must be borne in mind. Local intraspinal medication has given good results.

Syphilis and Exophthalmic Goiter.—Lévy-Franckel was one of the first (1911) to report improvement or the cure of exophthalmic goiter under treatment for suspected or certain syphilis. The exophthalmic goiter may be the precursor of tabes, and he has accumulated data to confirm that syphilis may be responsible not only for exophthalmic goiter but also for various pluriglandular syndromes.

Raynaud's Disease and Syphilis.—Giroux regards Raynaud's disease as often merely a manifestation of syphilitic disease of the arterioles.

Drop in Blood Pressure Under Arsenical Treatment.—Touraine warns that the "nitritoid crisis" is the result of the depressing influence of the arsenic on the blood pressure, saying that it can be easily warded off with epinephrin. The amount should be graduated to the dose of the arsenical preparation. His formula is one fourth as many milligrams as of centigrams of the arsenic.

Minor Practical Points.—Among those mentioned are the danger from intraspinal treatment in tardy syphilis. Tzanck emphasizes that a subarachnoid injection is practically merely an intralymphatic injection, all the drug being soon reflowed in the thoracic duct. On the other hand, an axis cylinder that has been touched with syphilis is more vulnerable than under other conditions. At most, he endorses injecting the drug by the vein, withdrawing lumbar puncture fluid at the same time. With tenacious secondary meningitis, however, intraspinal injections, he declares, are harmless and effectual.

*Cystoradiography. F. Leguen and E. Papin.—p. 733.

*Stretching of the Liver with Gallstones. M. Goullioud.—p. 735.

Bladder Radiography.—Leguen and Papin express surprise that the technic for pyelography has not been applied more systematically to the bladder. They have been using this cystoradiography, as they call it, since their publication on the subject in June, 1912, but found no reference to this method in the literature until Kelly's work in March, 1913. They have injected air, oxygen, bismuth, etc., but have found thorium sulphate or nitrate the best substances for the purpose. Thorium nitrate forms a solution which is not irritating or toxic, does not stain, and is less expensive than silver salts, etc. If a radiograph is taken of the bladder filled with the fluid, and then again after the bladder is emptied, any diverticulum shows up plainly, and this may explain the failure of persevering treatment, when cystoscopy has failed to reveal it. In one case two diverticula were thus revealed which had long maintained suppuration. Six instructive radiograms are given to show the different aspects of various lesions. A large tumor projecting into the contrast fluid renders the shadow within its outlines much lighter. In some cases the ureter mouth was gaping and the contrast fluid spread up through the congenitally dilated ureter, sometimes even into the pelvis.

Elongation of the Liver.—Goullioud describes with illustrations what he calls the *langnette hépatique*, or tongue-like projection of the liver, secondary to congestion and retention of bile from severe gallstone trouble, the heavy organs dragging on the liver, with extension to the liver of the processes of sclerosis. The corset may be an additional factor, but this localized hypertrophy of the right lobe of the liver has been found in men. It usually accompanies grave surgical gallstone disease and is an important sign of the latter. In any event, it should not be mistaken for the distended gallbladder.

*Eruption from Contact with Spoiled Grain. G. Romiti.—p. 941.

Eruption from Contact with Spoiled Grain.—Romiti reports several epidemics since 1915 of a papulous, eruptive dermatosis, with intense itching and high fever for from six to twelve hours. Only those persons were affected who had carried or otherwise handled grain subject to a special pathologic process, requiring the so-called scalding, or had handled flour from such grain, or clothing that had been in contact with it. In some cases the febrile eruption returned several times in succession, at intervals of three, five or seven days. Treatment was restricted to removal of the cause, hot baths and symptomatic measures.

Oct. 26, 1919, 26, No. 43

*U Incision for Abdominal Wall. G. Ruggi.—p. 1253.

*Reflex Dysmenorrhea with Ozena. I. Dionisio.—p. 1262.

*Mercury by the Vein in Grave Infections. S. Mello.—p. 1263.
Calcium Salts in Local Tuberculous Processes. Silvestri.—p. 1266.
Prophylaxis of Goiter in Italy. G. Pighini.—p. 1267.

U Laparotomy Incision.—Ruggi says that he was the first to make a transverse abdominal incision (published in 1890), and he now lauds the advantages in certain conditions of a large reversed U incision, the arms starting 4 cm. above the middle of the inguinal fold, and the curving line crossing the abdomen about 6 cm. above the umbilicus. This allows a broad flap to be turned back on the pubis. He explores the abdomen thus widely opened up, proceeding from the sound portions to the more pathologic areas. It answered requirements to an unexpected extent in a case described in which there were two fecal fistulas left from a gunshot wound.

Reflex Action from Ozena.—As the ozena subsided under treatment, the complete cure of the associated disturbances confirmed their reflex character. They included headache, nocturnal enuresis, tenesmus of the bladder, and dysmenorrhea.

Mercury by the Vein in Grave Disease of the Blood.—Mello as a last resort in three cases of puerperal or typhoid or other fever injected 2 or 3 mg. of mercuric chlorid by the vein twice in one day, and then for two days 4 mg. twice, and the apparently moribund patients recovered.

*Pseudo-Ileus from Ureter Calculus. C. Frugoni.—p. 1285.

*Fontana Stain for the Pale Spirochete. L. Nardelli.—p. 1288.

*Aneurysm of the External Iliac. A. Venturi.—p. 1297.
Serotherapy of Malta Fever. S. Spampinato.—p. 1299.

Pseudo-Ileus from Calculi in Ureters.—Frugoni reports three cases of this kind, the obstruction of the bowel stopping when the impacted calculus in the ureter was finally passed along. There is usually a history of more or less suggestion of kidney colics, and the cramps develop suddenly, diffuse or localized in colon or rectum, with tenesmus and pains suggesting a rectal tabetic crisis. The abdomen becomes distended and tender, and there is no passage even of flatus. A tendency to hydronephrosis clears up the diagnosis at once. Micturition is not modified but there is microscopic hematuria. The complete arrest of flatus and stools does not usually last more than two or three days, and then the symptoms subside as the calculus drops into the bladder or is expelled. In two of the cases reported his diagnosis saved the patients from a needless operation. The general aspect is less grave than with actual intestinal ileus; vomiting is rare and less insistent; the rectal tenesmus is accompanied by lancinating pains; and the meteorism is rapid and diffuse, without partial or segmental peristalsis.

*Multiple Fractures in Twelve Day Babe with Inherited Syphilis. S. Satanowsky.—p. 361.

*Infectious Purpura in Boy of Six. F. C. Garzón.—p. 369.

*Foreign Bodies in Children. J. C. Munyo.—p. 373.

Spontaneous Fractures in Young Infant.—Satanowsky describes a typical case of osteogenesis imperfecta which had entailed multiple and spontaneous fractures from the first day after birth and onward. The enlarged spleen subsided promptly to normal size under treatment for the inherited syphilis but the defective bones showed no change. Radiography shows less calcium salts than normal and that their distribution is irregular. The periosteum is not adherent to the bone below and the compact bone is much thinner than usual. At the age of 6 months the child was unable to sit up, and during a bath, the humerus fractured on both sides and the tibia on one, and the child died the next day, with fever. The ductless glands were of normal aspect.

Infectious Purpura.—In Garzón's case the boy of 6 presented a series of inflammatory foci in bone, extremely tender, but disappearing rapidly and spontaneously, and without a trace of fever at any time. The multiple accompanying ecchymoses and petechiae confirmed the presumptive diagnosis of infectious purpura. The child a few months before had required two operations for a traumatic abscess in the parietal region of the skull. The infectious purpura ran its course in a little less than a month.

Foreign Bodies in Children.—Munyo describes the extraction of a foreign body drawn into the trachea and three esophagus cases.

*Cysts in the Liver. R. Soto G.—p. 200.

Liver Cysts in Venezuela.—As a contribution to the debated question whether hydatid cysts occur in Venezuela, Soto describes a case of a solitary nonparasitic cyst in the liver and remarks that the turbid contents and the site differentiate these solitary cysts from hydatid cysts. The solitary cyst is generally accompanied by other congenital anomalies, and always with anomalies in the liver itself. His patient was a multipara of 46, and the abdomen was opened on the assumption of gallbladder disease. There had been symptoms from the liver cyst for fifteen years, and four punctures recently had evacuated 1 or 2 liters of fluid resembling bile at first, and later purulent. He was unable to remove the capsule of the cyst, as he attempted, and merely drained it after suturing it to the lips of the incision.

*Operative Treatment of Prolapse of the Uterus. F. Luque.—p. 97.

Influenza at Bilbao in 1919. A. López.—p. 101.

Treatment of Osteomyelitis. A. M. Arquellada.—p. 113. Conc'n.

Prolapse of the Uterus.—Luque gives fifteen illustrations of different ways of correcting genital prolapse, and says that in the more serious cases the results are exceptionally dependable with Wertheim's method of utilizing the uterus itself to reinforce the floor of the pelvis. The bladder then lies on top of the uterus. Wertheim has lately modified his

technic by pulling down the fundus of the uterus a little, which causes the cervix end to pivot up, and he sutures this cervix end to the sacro-uterine ligaments, thus holding the uterus slanting instead of horizontal, and the cervix at a point where it is impossible for it to work loose and sag down to the vulva.

*Accidental and Constitutional Psychoneuroses. E. Fernández Sanz.—p. 157.

History of Medicine in Spain. L. Lashennes.—p. 159.

*Treatment of General Paralysis. G. R. Lafora.—p. 161.

Psychoneuroses.—Fernández expatiates on the difference in the outlook between what he calls constitutional and accidental psychoneuroses. The constitutional is continuous, with waves of aggravation and remission, while other psychoneuroses are intermittent, with relapses, separated by periods of latency. The constitutional group includes hysteric and psychasthenic psychoneuroses; the accidental group includes the cases of neuropsychic asthenia, anguish and simple depression. The prognosis is better with this latter group. He warns in speaking to patients to avoid the term "constitutional" in this connection as liable to depress them.

Progressive Paralysis.—Lafora reiterates that three years of experience have convinced him that general paralysis in the first six months is capable of complete remission under appropriate treatment. (His latest report was summarized in THE JOURNAL, Dec. 6, 1919, p. 1808.) The main thing now is to detect it during these first six months or better yet, before it has induced the classic symptoms. This is possible by systematic periodical exploratory lumbar puncture, and he describes two cases in detail to show the importance of this. The two syphilitic men of 36 and 49 presented an almost identical clinical picture, insomnia, a tendency to aphasia and absentmindedness but no hallucinations, etc. As only two years had elapsed since infection in the younger man, the diagnosis of cerebral syphilis seemed certain in his case, while progressive paralysis seemed equally certain in the other case, the symptoms not coming on until twenty-three years after infection. But the lumbar puncture fluid told another story, the findings showing general paralysis in the younger man and merely vascular syphilis in the other—all confirmed by the later course of the cases.

Prensa Médica Argentina, Buenos Aires

Nov. 10, 1919, 6, No. 16

*Auricular Flutter. H. L. Caretti.—p. 157.

Activity of the Curare of the Amahuacas Indians. J. Guglielmetti and G. Pacella.—p. 160.

*Hematoma in Suprarenal Capsule. Bacigalupo and Perazzo.—p. 161.

*Brück's Precipitation Serochemical Test. Mazza and Barriga.—p. 162.

Hepatitis in Young Infant. A. Casaubon and J. Bacigalupo.—p. 163.

Auricular Flutter.—Caretti gives several tracings from a case of auricular flutter in a man of 64. The auricular flutter was scarcely modified in the least by a vigorous course of treatment with digitalis, which suggests that the condition will probably merge into heart block before long.

Hematoma in Suprarenal Capsule.—The hemorrhage in the suprarenal in the 4 days' infant proved speedily fatal. Some injury during the birth process was evidently responsible for it as also in Delucca's two cases in newly born infants with difficult delivery.

The Globulin Precipitation Reaction.—Mazza and Barriga report positive findings with the Brück globulin precipitation reaction, harmonizing with the Wassermann reaction in 78 per cent. of the 150 cases examined. They obtained a positive precipitation reaction with negative Wassermann only in two out of the 150. By estimating the results in less than twenty-four hours, the proportion of nonspecific reactions is much less.

Revista Médica del Uruguay, Montevideo

September, 1919, 22, No. 9

Obstetric Manikins. J. A. Beruti.—p. 663. See abstract p. 140.

*Chronic Constipation. C. Robertson Lavalle.—p. 680.

*Partial Tetanus. A. Rodríguez Castro.—p. 691.

*Hydatid Cysts in Uruguay. Victor Zerbino.—p. 695.

Surgical Constipation.—Robertson applies this term to chronic constipation rebellious to systematic medical treat-

ment, and describes the various surgical measures required for different conditions. He warns that the tissues should be kept from drying out by copious injections of physiologic saline. This is particularly necessary with operations on the colon, as absorption of water from the colon is thus prevented. He emphasizes the paramount importance of post-operative treatment, insisting in particular on ample supplies of water. This tends to reduce vomiting after general anesthesia, which puts such a strain on the sutures. After fixation of organs he keeps the patients in bed with the feet raised 15 cm. and feeds abundantly to fatten, guarding against gas production and the use of purgatives.

Partial Tetanus.—The young child developed fatal cephalic tetanus after an injury of the palate from a splinter of wood it had thrust into its mouth. This is the third case of partial tetanus recorded in Montevideo during the last eleven years.

Hydatid Cysts in Uruguay.—Zerbino remarks that the hydatid cyst is one of the scourges of Uruguay and is a national disgrace, as this is one of the most easily exterminated of diseases. In the public hospital of Montevideo the number of cases has increased from 11 in 1896 to 165 in 1915. The total figures include 216 cases in children representing 4.34 per cent. of the hospitalized children; the adults formed 1.32 per cent. of the total hospitalized. Throughout the country the proportion approximates one hospitalized case per five thousand inhabitants. The statistics show that the disease affects children and the young predominantly, up to the age of 30 or 35. The liver and lungs were the seat of the lesion in over 60 and 21 per cent., respectively, in children, and over 54 and 23 per cent. in adults; the brain in 3.82 per cent. in children; none in adults. Cases in adults are probably listed as cerebral tumors, etc. The bones were the seat in 0.83 per cent. in adults; none in children. Multiple localizations were found in over 3 per cent. in children; none in adults. In 106 children with hydatid cysts, the cyst suppurated in nearly 19 per cent.

Acta Scholae Medicinalis Univ. Imp. Kioto

- *Action of Nicotin on Muscles. K. Okushima.—p. 151.
- *Epinephrin and Heat Regulation. S. Kondo.—p. 169.
- *Autolysis of Vitreous Body. Y. Hijikata.—p. 207.
- *Sodium Oxalate, Citrate and Tartrate. S. Hara.—p. 213.
- *Agglutinability of Vibriones. T. Toyoshima.—p. 233.
- *Action of Gases on Muscle. A. Gohara.—p. 239.
- *Action of Epinephrin, etc., on Skeletal Muscle. K. Okushima.—p. 261.
- Histology of Corneoscleral Junction. K. Hiwatari.—p. 277.
- *Influence of Thyroidectomy on Gestation. T. Ukita.—p. 287.

Action of Nicotin on Skeletal Muscles.—Okushima's research on frogs indicates that nicotin excites the motor nerve terminals. Its action on muscle substance is first stimulating and then paralyzing. It is able to check the paralyzing action of curare to a certain degree.

Action of Epinephrin on Heat Regulation.—Kondo found the influence of epinephrin on the temperature negligible except when it was injected directly into the brain. By this route even a small amount sends the temperature up at once, unless this effect is checked with antipyrin or by long fasting. Intracerebral injection of saline or olive oil induces a very gradual rise in temperature, as also the subcutaneous injection of peptone and certain other substances.

Production of Lactic Acid in Autolysis of Organs.—The beef vitreous body contains lactic acid, and the amount increases during autolysis.

Toxic Action of Sodium Salts of Oxalic, Citric and Tartaric Acid.—Hara's research on mice demonstrated that the toxicity of these salts does not parallel their calcium-precipitating power, but this latter seems to be responsible for their action in enhancing the narcotic effect of magnesium sulphate.

Agglutination of Vibriones.—Toyoshima warns that non-cholera vibriones are liable to be agglutinated with cholera serum, and he theorizes to explain the reason for this. Exact differentiation, he reiterates, requires the Pfeiffer test reaction.

Electric Test of Action of Gases on Muscle.—Gohara describes the effect of electric stimuli on surviving mam-

malian nonstriated muscle under the influence of gases. The organ studied was the rabbit spermatic cord, and the gas was carbon dioxide. The electric apparatus devised for the purpose is illustrated. The gas displayed a paralyzing action.

Action of Epinephrin, Amins and Amino-Acids on Skeletal Muscle.—Okushima reports that epinephrin and the aromatic amins stimulate the skeletal muscle in small doses but paralyze it in higher concentrations. The action seems to be exerted on the terminal motor nerves.

Influence of Thyroidectomy on Gestation.—Ukita expatiates on the vast field for research on endocrine functioning by acting on the various ductless glands during pregnancy, and watching the effect on the fetus and on the progress of gestation. Thyroidectomy early in gestation in rabbits confirmed the intimate relations between the mother and the fetus, and that the thyroid is an extremely important factor in the development of the fetus and the normal course of gestation. The latter was prolonged to twice the normal time; the young were small and weak, and the centers of ossification abnormal, while the fetal thyroid gland was hypertrophied, and the development after birth was not regular. It is evident that the thyroid of the fetus has some activity even in the uterus, the hypertrophy suggesting a compensating process. This article is in English.

Archiv für Kinderheilkunde, Stuttgart

May 17, 1919, 67, No. 3-4

- *Fate of Syphilitic Children. E. Müller and G. Singer.—p. 161.
- *Acid Reaction of Blood in Relation to Albumin Requirement. Gertrud Fuhge.—p. 291.

Fate of Thoroughly Treated Syphilitic Children.—Müller and Singer review the experiences since 1909 when the first Welfander home for children with inherited syphilis was inaugurated in Germany. They devote nearly 130 pages to the tabulated findings year by year in 214 children who have been inmates of the institution, and call special attention to eighty-four who have been kept under surveillance for two, four, nine or ten years. All this material is classified according to treatment and other features of the cases. The data demonstrate that far better results were realized by this prolonged systematic treatment than by other means, but the final judgment will be possible only when the children get to be 30, 40 or more years old. But even already it is evident that the most serious consequences of congenital syphilis can be essentially attenuated or even completely cured. The mortality differed widely in different years; of late the children seemed to succumb to the syphilis itself and not to intercurrent disease so much as formerly, especially the infants. The total mortality among 202 syphilitic children was 22.8 per cent. The Wassermann reaction was negative on the final examination of the sixty-nine children given the full course of treatment. The children were given usually from seven to nine courses of treatment as they lived in the institution for three or four years.

The Acid Reaction of the Blood and the Albumin Requirement.—Fuhge relates that on the prevailing vegetable diet, with little meat, examination of the urine of 150 children in different children's asylums, all on the same day, showed an alkaline reaction, almost without exception. Only on the days with meat was the reaction neutral or acid. Five healthy children were given calcium chlorid, aiming to make the urine acid on the common diet. This was accomplished with 2 or 3 gm. in boys of about 12. These experiences demonstrate that calcium chlorid acts as an acid in the metabolism. This was evident from the increased ammonia content of the urine. Nothing was observed to indicate that the preponderance of an acid or alkaline reaction affects the nitrogen requirement, but the fact that calcium chlorid behaves as an acid suggests caution in its prolonged administration to children.

Correspondenz-Blatt für Schweizer Aerzte, Basel

Nov. 20, 1919, 49, No. 47

- *Apparatus Alleged to Help the Deaf. E. Oppikofer.—p. 1769.
- *Electric Accidents Affecting the Ear. F. Nager.—p. 1778.
- Epithelioma of the Trachea. T. Hug.—p. 1783.
- *The Protection Afforded by Influenza Masks. A. Lauterburg.—p. 1786.

Apparatus Claimed to Help the Deaf.—Oppikofer gives illustrations of his collection of twelve specimens of what he calls *schwindelhafte Ohrapparate*. He urges that similar collections should be in every ear clinic so that the deaf can see for themselves and have explained to them what frauds these "thermo-electric tympanums," audiphones, acoustiphones, electromagnetic microphones, etc., in reality are. The devices mentioned above cost, respectively, 75 francs, 20, 325 and 35 francs. Oppikofer declares in conclusion that these frauds not only obtain money under false pretenses but they are liable to do direct damage to the ear and cause the postponing of proper treatment in time for it to be effectual, and hence he thinks the state should forbid the advertising of such fakes. Some of the cantons in Switzerland have already imposed certain restrictions, but they are few and not always enforced. There is no federal legislation on the subject of quackery. Until all the states and neighboring states set energetically to work, these quacks that prey on the deaf will continue to reap their harvest.

Electric Injury of the Ears.—Switzerland has averaged from 50 to 100 serious electric accidents in the last few years and the number is increasing. Nager reports a case of injury of the ears from a live-wire accident, and summarizes four similar cases on record. Any part of the ear may be injured by the electric accident and the examiner afterward should bear this in mind as also the possibility of injury from the detonation alone, as the current is short-circuited. The detonation was regarded as the main factor in the personal case described, and the man was given 2,000 francs compensation for the unilateral cochlea injury.

Influenza Masks.—Lanterburg describes fifty-two sets of experiments which determined that the usual influenza masks are readily permeable for bacteria.

- *Pharmacology of Circulation in the Lungs. P. Wolfer.—p. 1817.
- *Rhino-genous Headache. E. Gallusser.—p. 1823.
- *Hallux Valgus. H. v. Salis.—p. 1833.

The Pharmacology of the Circulation in the Lungs.—Wolfer describes some devices with which it is possible to study the effect of different drugs on the circulation in the lungs. The data thus recorded apparently demonstrate that the intrapulmonary circulation is independent of the greater circulation. The two seem designed to supplement, compensate, and balance each other. Different drugs act differently on the two circulatory systems. For example, epinephrin seems to passively and perhaps also actively dilate the vessels of the pulmonary circulation.

Rhino-genous Headache.—Gallusser emphasizes that some long unsuspected nasal disease, which has never given any recognized subjective or objective signs of its existence, may entail headache for which no cause can be discovered. He describes a number of cases of this kind and warns of certain features that might suggest the clue. The headache is generally in the frontal region, a sense of oppression, a heavy feeling in the whole head, with occasional paroxysms of severe pain. The severe pain usually develops on arising in the morning (from change of position) and wears off later, but the headache may come on very severe at any hour after sneezing, bending over or emotional stress. This is liable to give the pain a misleading neuralgic character. Another symptom is the pain on pressure of the internal angle of the eye, over the frontal sinus. The most violent pains also are sometimes promptly and completely relieved by cocaine to the upper interior of the nose. This immediate relief by cocaine calls for exploratory opening of the frontal sinus. One man of 48 had had headache on the right side daily for ten years, incapacitating him at times, but none of the numerous physicians consulted had ever detected any symptoms on the part of the nose. No treatment had given any relief and he had been exempted from military service on account of habitual headache. Tapping the right side of the skull and pressure on the roof of the right orbit were painful. The middle turbinate was unusually thick. To get a better view, Gallusser pushed this turbinate to one side, and the patient exclaimed at the relief this afforded. This

encouraged high resection of the middle turbinate, opening the frontal ethmoidal cells and exposing the opening into the frontal sinus. Nothing pathologic could be detected, but the headache was cured once and for all. In another case long martyrdom from headache was cured by opening up the frontal sinus although nothing pathologic could be detected in it except that it was extremely sensitive to the probe. This woman of 44 tried to commit suicide on account of her headaches, which by exclusion had been long qualified as nervous. In neither of these two cases was any sign of suppuration found.

Treatment of Hallux Valgus.—Salis reviews his experience with 286 cases of hallux valgus and describes his successful conservative treatment of the milder forms.

An Esophylactic (Protective) Function of the Skin.—Hoffmann has been much interested in Bruno Bloch's opinions on "Dermatology in Relation to Problems of Metabolism and Immunity," as expressed in a course of lectures delivered at the University of Zürich. He believes, with Bloch, that the skin has an important biologic function that has not been fully recognized. By virtue of this function the vital organs are protected to a great extent against disease germs. This he regards as one of the main points of contact between dermatology and general medicine. Bloch had been led to the consideration of this question by the results of the recent investigations on the allergic reaction of the skin in trichophytosis, tuberculosis and syphilis. Bloch emphasizes that the skin plays the most important part in the phenomena of allergic immunity and of hypersusceptibility, whereas in tetanus, diphtheria, etc., the blood is the carrier of the prophylactic forces. This may perhaps be compared to the protection afforded a country by its land and naval forces. The fact that when the skin is extensively affected in tertiary syphilis and lupus, the internal organs so frequently escape, and the part played by the skin in overcoming exanthematous infectious diseases, sustain this assumption. But more especially the recent investigations of the allergic function of the skin, together with the undeniable therapeutic effect of general light baths, lead Hoffmann to believe that the skin must produce immunizing materials that exert a healing influence for, in view of the slight penetrability of the short-wave rays used in phototherapy, he can find no other explanation. Owing to its importance in connection with biology and general pathology, he reports in detail the various angles from which he has viewed the assumption of such a distinct function of the skin, thinking that the hypothesis would have at least heuristic value, that is, might incite others to research.

Effect on Growth of Lack of Minerals in Food.—Grabley remarks that all admit that the restricted war diet was the cause of many disturbances of growth and metabolism, but all are not agreed as to exactly what ingredients were lacking in this diet. Many emphasize the lack of variety, others the deficiency in fat and protein, others the absence of vitamins. Very few mention the metabolism of mineral substances, but this, Grabley thinks, is of vital importance. The normal functioning of the cells, as has been shown by the study of the cell nucleus, depends on the optimal isotonicity of the cell fluid. To insure this, necessary mineral sub-

stances must be present. Various deficiency diseases result partly no doubt from the lack of vitamins, but even more from the lack of mineral substances. Schiff ascribes edema to extensive damage to the cell structure which upsets the water balance in the body and causes faulty metabolism of mineral substances. Grabley holds that just the reverse is true; namely, that the faulty metabolism of mineral substances in the cell is due to the deficiency of these substances in the diet. The demineralization of the cell produces the water imbalance, causes extensive damage to the cells, interrupts cell functioning, and finally destroys the cell nucleus and the cell. Grabley cites in support of his views the conclusion reached by R. Berg, the physiologist and chemist, to the effect that hemophilia is due to a disturbance of the balance of mineral substances in the blood. Grabley accepts the theory that the sources of energy in the animal organism, in short, life itself, are derived from electrochemical and electrophysical processes. Purely organic substances and their solutions remain chemically and physically inactive until they are mixed with inorganic salts; then the chemico-physical and the electrolytic processes in the cell fluid begin; hence the importance of inorganic salts in the human dietary.

Nerve Grafts.—Eden reports an unsuccessful attempt at nerve grafting after a shell wound of the right arm. The wound healed but left radial paralysis. The radial was laid bare and a defect 10 cm. in length was discovered. A corresponding segment of a popliteal nerve from an amputated limb was used to bridge the gap, the transplant being fixed by means of fine epineural interrupted sutures and embedded in healthy subcutaneous tissue at a safe distance from the scars. The wound healed promptly, but the after-treatment by means of electricity and massage was without result. Nine months after the original operation the region of the transplant was reopened. The transplant bore little resemblance to a nerve but looked more like a rough strip of connective tissue. The transition from the nerve to the transplant was gradual, so that the ends of the transplant could not be definitely located. Stimulation by means of a strong electric current brought no reaction. The transplant was therefore removed and the peripheral end of the nerve was grafted into the median.

Injection of Air Into the Peritoneum for Roentgenoscopy.—Von Teubern thinks this method of pneumoperitoneum has considerable value. The procedure is, however, somewhat painful, and its use will doubtless be confined to cases in which other, less painful methods have not accomplished the desired result.

Treatment of Erysipelas.—Bardachzi did not find colloidal silver preparations, radium, etc., effectual in the treatment of erysipelas. He believes that none of the specific methods are superior to conscientious symptomatic treatment. He recommends compresses moistened with dilute Burow's solution and laid on the affected parts, and prescribes acetylsalicylic acid several times a day. In all severe cases digitalis is indicated. The results of this treatment in 183 cases lead Bardachzi to believe that no specific treatment will accomplish more.

Undernutrition in Relation to Osteoporosis and Osteomalacia.—Twenty-six cases of a disease of the bones were observed at Frankfort-on-the-Main between March and June,

1919. The age limits were 19 and 72, 65 per cent. of the 23 women being of the climacteric and postclimacteric age. The women were of the poorer class, and 16 of the patients admitted their nourishment had been deficient; namely potatoes, turnips, thin soup, war bread and the small meat ration. Milk, eggs, cheese and butter were lacking. Most of the women weighed under 110 pounds. In many, emaciation was far advanced; 7 had had rickets, 15 presented curvatures of the spine. Some were confined to bed. Spontaneous fractures had occurred in 10 cases. Dragging the feet was common. Alwens describes these conditions at length and his diagnosis is osteoporosis from undernutrition (deficiency of protein, lime and phosphorus). The rapid development of the pathologic symptoms, the effects on the thorax and the spine, and the lack of typical pelvic changes were features differentiating the syndrome from osteomalacia, though the clinical picture suggested osteomalacia, and this may develop later. In osteoporosis Alwens recommends a diet of high caloric value, with special attention to the protein, calcium and phosphorus content. Phosphorus in 0.5 mg. doses, three times daily, taken with cod liver oil, was found helpful. Calcium lactate, 3.0 gm. daily, is also indicated. Epinephrin did not prove beneficial. Prompt, distinct and continued improvement usually followed treatment.

Specific Typhus Skin Reaction.—Friedberger and van der Reis relate that an emulsion of the bacillus with which the agglutination test is made in typhus induces a pronounced inflammatory reaction when injected subcutaneously in the healthy and in diseases other than typhus, but there is no reaction in typhus patients. The lack of the usual reaction is thus a sign of the presence of typhus. They call the bacillus used the Weitz-Felix bacillus X 19. (The bacillus used commonly for the agglutination test is the proteus X.)

- *Heart Disease and Pregnancy. K. Kautsky.—p. 559.

Basal-Cell Uterine Cancer.—Krompecher's article is based on 216 cases of uterine cancer. He was surprised to find that 75 per cent. of them represented basal cell cancers. He classifies this material, with several plates, showing the histology and origin. The solid type formed 63 per cent., while types such as are found mostly on the skin were very rare.

Roentgen Technic.—Winter writes from the Munich gynecologic clinic to extol the progress realized in radiotherapy and radiotechnic with the introduction of tubes of the Coolidge type with which he has been working since May, 1916.

Viability of the Prematurely Born.—Schmitt relates that 316 children weighed only from 700 to 2,200 gm. among the 8,881 born at the Würzburg maternity hospital in ten years. The mortality before the end of the year in this small group was 78 per cent. The smallest child that survived weighed 1,100 gm., but it is absolutely exceptional when a child survives that weighs under 1,500 gm. Even those that weigh from 1,500 to 2,000 gm. have very feeble vitality so that at most 25 per cent. survive the first year. There is no special physical inferiority for which the small weight can be incriminated. With children over 2,000, the prospects are favorable for 50 per cent. surviving.

The Limit of Viability of the Prematurely Born.—Ahlfeld reviews the literature on the nineteen smallest and earliest born infants that have been recorded. The periods of gestation were from the twenty-fourth to the thirtieth week, and the weight ranged from 500 (the tenth day of life) to 1,000 gm. He tabulates the details, and concludes that 750 gm.

at birth can be accepted as the lowest limit possible for a child to survive.

The Uterine Adnexa and the Appendix.—Beuttner takes nearly ninety pages for his data and arguments against systematic appendectomy as a routine supplement to operations on the adnexa. Microscopic examination of the appendix in eighty-seven cases in which this had been done showed that the appendectomy had been actually indicated only in four of the cases.

"Pregnancy Dropsy."—Zangemeister discusses the course and the connection between hydrops gravidarum and kidney disease or eclampsia, as he studied it in 193 cases of "pregnancy dropsy." In the first place, he declares, the tendency to dropsy should be combated by avoiding ill ventilated and dusty air, chilling of the skin, constricting clothing, over-exertion, excesses in eating and drinking, especially of salt, not lying in bed too long, and not taking drugs which might injure the blood or vessel walls. These measures are particularly necessary if there is any tendency to slight edema, and if there has been a tendency to dropsy in a former pregnancy. When a tendency to slight dropsy has become apparent, but there is as yet no rise in blood pressure and no albuminuria or preeclamptic symptoms, then bed rest and restriction of the intake of fluids generally suffices to banish the hydrops, but this is not permanent until the weight has gone down under increased diuresis. This of course does not cure the causal abnormal permeability of the capillary walls, but the restriction of intake of fluids helps this by relieving the load in the vessels. The patients bear this well if the intake of salt is reduced, and also of solid foods, to keep the thirst down and relieve the metabolism in general.

There does not seem to be retention of salt by the kidneys, but its harmful influence is manifest in other ways. He warns against digitalis as not required in the mild cases, and as liable to bring on eclampsia in the grave cases. He saw this occur in two cases, the blood pressure running up and the convulsions developing. Measures to induce sweating never did harm in his experience. The special benefit from them he ascribes to the different distribution of the blood which they realize. He warns not to attempt the sweating procedures if the blood pressure indicates impending eclampsia. Decapsulation of the kidney may be considered in extreme cases, but not with developed eclampsia. Venesection and lumbar puncture may be necessary, or evacuation of the uterus. "In established eclampsia, reduce the pressure on the brain, reduce the tissue hydrops as the cause of the brain swelling responsible for the pressure, and fight off the attacks of high blood pressure which start the convulsions anew, but the first thing is to empty the uterus."

Heart Disease and Pregnancy.—Kautsky emphasizes that a pregnant woman with mitral stenosis, on account of the increased area of the circulation, is kept constantly in conditions like those of a nonpregnant woman continuously at hard work, day and night. Fully 40 per cent. of the pregnancies with mitral stenosis terminate in spontaneous abortion or miscarriage. He bases his treatment on these facts, and especially on his repeated experience that the demands even of a normal, uncomplicated pregnancy are enough to upset the compensation with a valvular defect.

Remuneration of Sick-Fund Physicians. Vrendenberg.—p. 986.

*Cancer of Both Fallopian Tubes. T. B. Phillips.—p. 988.

Nervous Manifestations Complicating Influenza.—Klessens states that he encountered many pathologic nervous conditions associated with influenza, such as brachialgia, sciatica and persistent paresthesias. One patient gave evidence of encephalitic foci in the medulla oblongata, and transverse cervical myelitis occurred in another. Klessens ascribes the condition to one or more foci at the bulb. An apparent case of encephalitis pontis was noted. The left-sided paresis of the leg with exaggerated Achilles tendon reflex and diminished skin reflexes; the disturbances in hearing and the

hypalgnesia in the trigeminal region suggested a pons lesion. Another patient presented dizziness, deafness, nystagmus, and falling backward when the eyes were closed. Here the lesion may have been in the cerebellum, though the fact that the direction of the falling was not affected by the position of the head speaks against this assumption; in this case there had been a middle ear infection. The conditions found in one case—dizziness, nausea, nystagmus to the right, a falling sensation, and deviation to the right in walking—Klessens ascribes to a lesion of the cerebellum. A child of 8 presented an especially interesting case of a lesion of Purkinje's cells, caused by the toxins of the influenza virus. The nystagmus, the disturbance in speech, the static ataxia and the dysidiadokokinesia form a syndrome that points to the cerebellum.

Height and Weight of Children.—Van der Loo tabulates the relative height and weight of 598 children between 6 and 12. He found thirty-one "scrofulous" children who averaged 0.35 kg. less in weight than the others, and seventy-five weak children, who averaged 1 kg. less. In children of a given age there was a divergence of about 6 kg. in weight and 30 cm. in height. The taking of height and weight awakens rivalry and serves as an aid to parents and physician in bringing weak children up to standard. A weight more than 1 kg. below the average is an indication for a careful examination of the child. The height is not so significant as the weight, as the divergence is much greater.

Cancer of Fallopian Tubes.—Phillips' patient, an unmarried woman of 44, was still menstruating regularly, and the bilateral presumably primary papilocarcinoma of the fallopian tube was discovered only by chance. For about a year she had had a whitish, foul-smelling discharge from the vagina. There was no admixture of blood, but she felt herself growing weaker and was losing weight, and there was slight pain in the lumbar region. She had been referred to the hospital for atresia of the vagina, and an occluding membrane was discovered in the vagina. The uterus could not be distinctly outlined but on each side a growth was palpable apparently arising from the ovaries. The growths were removed by a laparotomy on the assumption of bilateral hydrosalpinx.

Ugeskrift for Læger, Copenhagen

Nov. 27, 1919, 81, No. 48

*Action of Small Doses of Roentgen Rays. Hjalmar Eiken.—p. 1849.

Action of Small Doses of Roentgen Rays.—Eiken has been experimenting with roentgen treatment in doses so small that the action of the rays seems to be restricted merely to a stimulating influence. Laboratory animals and fowls were treated in this way daily for months and then every third day up to a year, and none showed the slightest sign of injury therefrom. Their growth and procreation proceeded normally and their young procreated normally in turn. Similar experiments with animals inoculated with tuberculosis demonstrated that the reaction of the tissues to the tubercle bacilli occurred earlier and was more active than in the controls, the incipient foci healing. Applying these results to human beings, there seems a prospect of aiding the cure by this means in persons who display only a sluggish reaction, or the focus is located at a point where experience has always shown a torpid course. Without removing the clothing, the exposures were made for one minute from the front and from each side and for seven minutes from the back, and repeated every day or second day. The dose was $\frac{1}{100}$ and $\frac{1}{200}$ S. N. tablet. He gives the details of three cases of tuberculosis in which this treatment was applied. The stimulating action from it was unquestionable. The patients were 15 and 18 years old. In the superficial lesions the increased blood supply to the focus, the increased secretion and more pronounced demarcation were manifest, and then healing followed. One of the patients had tuberculous processes in lungs, cervical glands, in skin and in the tibia, with several fistulas. A total of 100 exposures were made, and all the fistulas and external processes healed. The bacilli disappeared from the sputum for a long time, but scanty bacilli have appeared in the sputum again recently.

THE CLINICAL RÔLE OF THE FAT-SOLUBLE VITAMIN: ITS RELATION TO RICKETS*

ALFRED F. HESS, M.D.

AND

LESTER J. UNGER, M.D.

NEW YORK

In the last few years, the subject of deficiency diseases has become one of absorbing interest for both the laboratory investigator and the clinician. In order that the advances in this field may proceed on firm ground, it will be necessary that step by step we compare and correlate experimental results with clinical experience. Perhaps the largest amount of work has been carried out on scurvy, both in this country and abroad, and has brought forth results that coincide remarkably for animals and for man. All diets leading to scurvy in the guinea-pig produce scurvy in man; all antiscorbutics are potent for both species; all signs and symptoms of the disease are common in some degree to both guinea-pig and man. There is, however, one important difference, namely, that in man the disorder is a slow, markedly subacute process, whereas in the guinea-pig it is almost an acute disease. This does not mean that this animal is not suitable for the study of scurvy, but merely that it is a hypersensitive reagent, and therefore not well adapted for fine quantitative experiments.

We shall not dwell on scurvy at length, confining our attention rather to so-called deficiency diseases that have been less fully developed. We should like to say a few words in general, however, about antiscorbutic foodstuffs. There is a widespread impression among laymen, hygienists and physicians that the drying of foods or their subjection to high degrees of heat necessarily destroys their antiscorbutic potency. It is important to realize that, although holding good in most instances, these results are not based on a biologic principle, for we are approaching a time when dried foodstuffs probably will be made wide use of. It has been shown by Holst and Froelich, Cohen and Mendel, and others, that under certain conditions vegetables may be dehydrated and retain their antiscorbutic value for months or years. It is likewise true that milk may be dried and yet preserve by far the greater part of this accessory factor. In two cases we were able to cure infants of scurvy by means of milk that had been dried by the Just process, and to protect them as long

as they were under observation, for at least three to seven months, by a dietary containing no further antiscorbutic food. It may be added that drying fixes the antiscorbutic principle, bringing it into a more permanent and resistant state, much as it does toxins and antitoxins. For example, milk that has been quickly dried by this method partially withstands subjection to 120 C. for one hour, whereas fluid milk loses practically all antiscorbutic virtue when heated to the same degree.

We shall not pursue this aspect of the subject further, but would point out that a most important factor, and one until recently entirely disregarded, is that of the original content of the foodstuff in antiscorbutic vitamin. Whether we consider vegetables or milk we cannot regard these foods as possessing a standard antiscorbutic value—not even in an approximate sense. It is therefore inexact and misleading, unless this limitation is borne in mind, to frame a table of the relative antiscorbutic content of the various foodstuffs. The milk will vary according to the fodder of the cows and again according to its age, especially if it has been subjected to pasteurization. The vegetables will vary according to their maturity and age previous to being cooked or dehydrated. Therefore, until improved methods are devised, we should endeavor to use young and fresh vegetables for purposes of dehydrating.

CAUSATION OF RICKETS

An investigation of scurvy naturally led to a consideration of a disorder which, from a clinical standpoint, has always been linked with scurvy. We refer to rickets. This is the most common chronic disorder among infants living in the temperate zone. It occurs more particularly among the poor, but is very common in moderate degree among the infants of the well-to-do. In an infant asylum with which we are connected, more than 90 per cent. of the infants show some degree of rickets. The theories as to its pathogenesis and etiology are manifold. Most of these may be grouped into one of two classes: those which place the onus on poor hygienic surroundings and those which regard the disorder as of dietetic origin. Under defective hygiene is included lack of sunlight, of fresh air and of exercise; the "domestication theory" of von Hansemann, the respiratory poison theory of Kassowitz. The dietary theory includes the fat deficiency, the alimentary intoxication theory, and newest of all, the vitamin deficiency. The last hypothesis was brought forward from a theoretical standpoint by Funk, and more recently has been sustained by Mellanby¹ as the result of experiments on dogs. The latter believes that he has shown that if dogs are deprived of the fat-soluble vitamin

* This work was carried out in part on a fund provided by the New York Foundation.

1. Mellanby, E.: *Lancet* 1: 407 (March 15) 1919.

they develop rickets, whether they are allowed at large or kept in confinement. These conclusions of Mellanby have been accepted by Hopkins and Chick in a memorandum drawn up by a committee on accessory food factors appointed jointly by the Medical Research Committee and the Lister Institute.² This report considers the fat-soluble factor as synonymous with the anti-rachitic factor, and even constructs a table of anti-rachitic foods, arranging them in three different grades. This memorandum was prepared for the guidance of those engaged in the administration of food relief to famine-stricken districts.

This is the status of the etiology of rickets, now, almost 300 years since Glisson's classic description. You will see that there has been no advance, with the possible exception of the introduction of the vitamin hypothesis. The subject of rickets can be well studied on infants, owing to its great prevalence. But to our knowledge there has been no systematic study of a group of infants carried through for a long period. This is due in part to the fact that an investigation of this kind is impossible in the hospital, in the dispensary or in the home, but can be carried out only in an institution where the hygienic and sociological conditions are alike for the entire group, and where all factors are

Scorbutic Beading						Diet
Age. (mos.)	Beading	Epiph	Age. (mos.)	Beading	Epiph

6	+++	++	7	++	+	
7	+±	+	8	±	±	O.J. added (15 c.c. daily)
9	+	+	9	±	±	

Chart 1.—Scorbutic beading: Two cases (I. M. and I. L.) demonstrating beading of the ribs of scorbutic origin. This sign developed in spite of a dietary that included cod liver oil, and decreased rapidly when orange juice (15 c.c.) was added; ± signifies the least and +++ the maximum degree of beading.

under absolute control. About a year and a half ago we undertook the study of rickets in about 100 infants cared for in a modern child-caring institution. These infants lived under excellent hygienic conditions, their nursing and care was the same, their food was prepared in a central diet kitchen, and they remained in the institution for the entire period of observation. Once a month they were examined for rickets. This included notation as to the size of the fontanel, the beading of the ribs, the enlargement of the epiphyses, the condition of the musculature, the eruption of the teeth, the static development, etc. They were placed on various diets—an abundance of fat and fat-soluble vitamin in the form of milk and cream; a deficiency of these substances, as in skimmed milk; an abundance of water-soluble vitamin as supplied by autolyzed yeast; or diets such as Mellin's Food or condensed milk. In all cases there was but one deficiency in the diet, which was adequate in quantity, that is to say, in its caloric content, and contained in every instance sufficient antiscorbutic foodstuff.

It is realized that a test of this kind should be carried out for a period of years, and that it is, therefore, premature to lay down rigid conclusions as a result of this work. However, after a period of observation of this

length, it is possible to draw some conclusions. It is all the more important to discuss this question, as the laboratory results are absolutely at variance with the opinion of most clinical observers, who believe that rickets commonly follows overfeeding. In a study of this kind, what is to be the criterion of rickets? There is no delicate indication of what may be termed latent or subacute rickets, which can be recognized only by metabolism tests. But this mode of approach is handicapped by the fact that such tests generally can be carried out for only short periods, whereas the disorder itself is one of marked chronicity, with irregular periods of advance and of quiescence. Furthermore, they are so laborious as to permit of an investigation of only a small number of cases. After a preliminary study it seemed that beading of the ribs, especially in conjunction with the enlargement of the epiphyses, furnished the most reliable criterion of the course of the disease. We turned, therefore, to an intensive study of beading of the ribs.

It was found that six grades of beading could be distinguished, and these have been designated in the charts by means of plus signs. It may be thought that this empiric method would be very inexact. However, it was found that if the examinations were carried out always by the same person, remarkable uniformity could be obtained. We shall not weary the reader with a detailed discussion as to the clinical varieties of beading of the ribs, but shall report on this question at some other time.³

Physicians in general, and pediatricians as well, regard beading of the ribs as a pathognomonic sign of rickets. Some time ago in studying infantile scurvy we noted not only that there was marked beading in connection with this disorder, but also that very often the beading or rosary quickly became less or disappeared when orange juice or other antiscorbutic food was given (Chart 1). In other words, *there is not only rachitic but also scorbutic beading*. This conforms with observations in experimental scurvy. It was pointed out by Jackson and Moore, and has been noted by various other investigators, that beading of the ribs occurs in the course of the experimental scurvy of guinea-pigs. This has been referred to generally as "pseudorachitic" beading. In point of fact, it must be regarded as truly scorbutic, as it shows the various microscopic appearances of scurvy. As we have stated, this sign has its counterpart in infantile scurvy; to a less extent, the same is true of enlargement of the epiphyses. That beading of the ribs may be of scorbutic origin is of interest, from both a clinical and an experimental standpoint. Probably this fact is largely accountable for the confusion that existed between infantile scurvy and rickets, and led to the former being regarded as "acute rickets," previous to the publications of Barlow. It is owing largely to this sign that the diagnosis of rickets has been made so constantly in association with infantile scurvy; the data of the incidence of rickets in scurvy have been based mainly on the occurrence of the rosary. It may have brought some confusion also into the study of experimental rickets. We have encountered similar beading, with slight hemorrhages of the costochondral junctions, in the scurvy of dogs. In the light of this experience it should be

3. It may be said in passing that beading may be of various kinds—round or angular, that is to say, more cartilaginous or more osseous. It may be of a chronic nature—"residual"—resembling the enlargement of the epiphyses found in guinea-pigs that have been cured of scurvy. In order to make correct use of this sign it must be thoroughly studied and its modifications appreciated.

2. Hopkins, F. G., and Chick, H.: *Lancet* 2: 28 (July 5) 1919.

noted that three of the four diets that Mellanby made use of in his experiments on rickets in dogs contained no antiscorbutic whatsoever, and that the fourth dietary included only 3 c.c. of orange juice daily, a quota of antiscorbutic food that is insufficient. We do not, however, wish to imply that he was dealing with scurvy rather than with rickets.

Beading of the ribs may also come about as the result of a lack of the water-soluble vitamin. This

Chart 2.—This infant (J. C.) was admitted when 1 week old and developed marked rickets on diet containing large amount of fat-soluble vitamin (milk and spinach); improvement in rickets and general condition when cod liver oil was given.

takes place less frequently than in scurvy and far less frequently than in rickets. This sign was noted in infants who were receiving only a small quantity of the water-soluble factor in their dietary, and who later were given considerable amounts of autolyzed yeast. In some of these cases there was an unmistakable sharp decrease in the rosary. It is interesting to note that beading of the ribs has been observed at postmortem examination in cases of infantile beriberi. Andrews⁴ writes that among eighteen cases of infantile beriberi, a disorder brought about by a lack of water-soluble vitamin, he encountered three instances of beading of the ribs. He also has stated, in a personal communication, that these were the only instances of rickets that he encountered at necropsy in the Philippines. Probably beading does not occur with greater regularity in the course of infantile beriberi because most of the children die during the first two months of life. It becomes all the more clear that in a study of rickets, whether in infants or in animals, it is essential to have the diet complete, except for the one factor under investigation, and especially that it should contain adequate amounts of the antiscorbutic and of the water-soluble vitamin.

At the outset of our investigation, attention was directed to the influence of hygienic and nondietetic measures on the development of rickets. It was found that rickets can develop notwithstanding an abundance of fresh air. It occurred in the larger and in the smaller rooms of the institution, and developed in infants at the tuberculosis preventorium, an institution in the country where particular attention is paid to outdoor treatment. It was found likewise that a liberal allowance of light could not prevent the development of this disorder. Infants in glass cubicles were not spared more than those in the regular wards. With this question in mind, in the spring of 1917 five children were given daily treatments of violet ray, the

mercury vapor quartz lamp being used for this purpose. Their entire bodies were exposed for twenty minutes, so that they soon became brown, as if well tanned by the sun. This therapy, which was carried out with regularity for three months in infants about 1 year of age, did not lead to a definite improvement in the rickets, nor did it benefit their general condition. Violet ray treatment cannot be considered the equivalent of heliotherapy. But the fact that rickets is exceptional in the arctic region, where there is a lack of sunlight for the greater part of the year, is a strong argument against its predominant influence.

INFLUENCE OF FAT-SOLUBLE VITAMIN

As we have stated, discussion as to the etiology of rickets centers at present about the fat-soluble vitamin. We shall therefore direct our attention to this aspect of the subject. This vitamin, as is well known, has been shown by McCollum and his co-workers, and by Osborne and Mendel, and others, to be present in abundance in animal fats—such as cream, butter and eggs—as well as in the leafy vegetables, but to be absent or almost absent in the vegetable oils. As far as has been demonstrated, it cannot be synthesized by the animal body.

In order to provide an adequate amount of this important dietetic factor, we placed a number of infants, during the first months of their lives, on large amounts of milk, in some instances giving cream in addition. By this means, if fat-soluble vitamin is the controlling influence, the development of rickets should have been prevented. In some cases, with this dietary, which it will be remembered included also orange juice, a very mild degree of rickets was observed, but in others marked signs developed. For example:

CASE 1.—J. C., a baby admitted when 1 week old, without rickets, was given daily when 3 months old a quart of milk containing fully 3 per cent. of fat. By the middle of November when he was 5 months old, he had developed marked

Chart 3.—Weight curve of case of marked rickets shown in Chart 2 (J. C.); inability of large amounts of milk and spinach to produce gain in weight; marked increase on addition of cod liver oil.

rickets. His general condition had improved during these months, he having gained 2 pounds in weight. Rickets persisted for ten months, in spite of this large amount of milk, and until cod liver oil was given in October (Charts 2 and 3).

Consider a case such as the following:

CASE 2.—A well nourished baby, aged 2 months, was given a formula containing 24 ounces of milk; it received also orange juice and later some wheat cereal. Rickets developed

on this diet with all the typical signs. In the fall, when it was 10 months old, the rickets diminished without change of diet.

Rickets has developed in several instances on 24 ounces daily of protein milk (containing about 2.5 per cent. of fat) and even in nursing infants, whose mothers were on a diet that included a large quota of milk, butter and vegetables.

It is difficult to bring these observations into harmony with the hypothesis of a lack of fat-soluble

Chart 4.—These five infants received a diet that was complete in every particular except for the fat-soluble vitamin. It consisted of highly skimmed milk (Krystalak, 0.2 per cent.; fat, 180 gm.); sucrose, 30 gm.; cottonseed oil, 30 c.c.; autolyzed yeast, from 15 to 30 c.c.; orange juice, 15 c.c., and cereal. The monthly examinations of beading of the ribs represented by the plus signs below the heavy line refer to the period of fat-soluble vitamin deficiency; ± signifies the least degree of beading, and +++ the maximum. These cases show that beading decreased rather than increased in spite of this deficiency.

It should be understood also that these babies at no time had symptoms of indigestion—vomiting or diarrhea. It may be argued that the content of fat-soluble vitamin in the milk was small, owing to a deficiency of this factor in the fodder of the cows.⁵ This suggestion is attractive, as it has been noted not only by clinicians, but likewise by pathologists, that cases of rickets are most numerous in the spring months and decrease in number and severity in the fall. This phenomenon, brought out sharply by Vogel and by Kassowitz, should be strongly emphasized; indeed, any explanation of the etiology of rickets, in order to be convincing, must explain the striking seasonal variations. This peculiar incidence stood out in relief in the course of the monthly physical examinations, as they proceeded from the spring to the fall. Without any change in the diet the rickets decreased in September or October. In view of this fact, animal experiments should be so planned that those of a curative nature bring about the cure in the spring, whereas those which are provocative should lead to the development of the disorder in the fall. We are willing to admit that milk must be different when secreted by cows on pasture than when the fodder contains almost no greenstuff. This does not, however, indicate that this change brings about the cure of rickets, and least of all that it is the fat-soluble vitamin that deserves the credit. It does

5. The subsidence of rickets depending on the nature of the fodder of the cows could be construed as follows: The cows are sent out to pasture about the middle of May. At first some of the vitamin goes to make up for the deficiency of their tissues in these factors, resulting from the stall-feeding throughout the winter. Somewhat later the vitamins are secreted to a large extent into the milk. We must furthermore allow two or three months for the subsidence of the rachitic signs for the improvement to become evident clinically. Reasoning thus, we account for the four month period—from the middle of May to the middle of September—the long interval between the time of the change to green fodder and its effect on the nutrition of the baby.

not account for the large number of babies receiving an abundance of milk who develop rickets, while others taking a far less quantity of the same milk remain almost normal; nor for the cases, by no means infrequent, of well nourished breast-fed babies who develop the disease, in spite of the fact that the diet of the mother contains a large amount of the fat-soluble factor.

RESULTS OF TEST DIET

But let us approach the question from the other side. Do infants who receive very little fat-soluble vitamin in their diets become rachitic? In order to answer this question, five infants were put on a dietary that was complete in every respect except for a lack of this principle. The dietary was composed of 180 gm. of Krystalak, a commercial preparation of highly skimmed milk which, when diluted tenfold with water, has a fat content of less than 0.2 per cent. In its preparation the milk is first heated in a vacuum to 130 F. for fifty minutes and then dried by the Just process at a temperature of 212 F. for twenty seconds. This milk was sweetened with 30 gm. of sucrose. Fifteen c.c. of orange juice were added to supply the antiscorbutic vitamin, 30 c.c. of autolyzed yeast to furnish water-soluble vitamin, 30 c.c. of cottonseed oil to provide fat, and wheat cereal (cream of wheat) when the age of the infant required this addition. The babies were from 4 to 9 months of age, and somewhat below the average in physical development. They should have developed rickets if a lack of fat-soluble vitamin is the essential cause of this disorder. They have been on this diet for periods varying from five to nine months, have been weighed daily and examined frequently, and show no greater signs of rickets than the average baby in the institution—merely such minor manifestations as are rarely lacking (Charts 4 and 5). This result shows that this vitamin is not the much sought for antirachitic factor; that it cannot bear the same direct relationship to this disorder as do other vitamins to their specific diseases—we refer to scurvy and to beriberi. Even if rickets is in some degree

Chart 5.—Epiphyses: The same five patients as in Chart 4, receiving minimal fat-soluble vitamin and illustrating enlargement of the epiphyses instead of beading of ribs. These cases show that according to this sign rickets did not develop on a lack of fat-soluble vitamin.

influenced by a fat-soluble vitamin deficiency, there are more important and dominating factors that determine whether or not the disorder shall come to pass.

This test diet (minimal fat-soluble vitamin) is of interest from a point of view quite apart from rickets. As is well known, experiments carried out by Osborne and Mendel and by

McCollum have shown that if rats receive no fat-soluble vitamin in their diet, they cease to grow and develop a disease of the eyes, termed xerophthalmia. A similar eye disease was reported some years ago in Japan by Mori,⁶ and more recently by Bloch⁷ of Copenhagen, as the result of a diet of skimmed milk

6. Mori, M.: *Jahrb. f. Kinderh.* 59:175, 1904.

7. Bloch, C.: *Ugesk. f. Læger* 70:309, 1917.

and a deprivation of milk fat. These laboratory and clinical reports have caused physicians and hygienists to take alarm and to utter vague warnings of the great danger that lurks in a diet deficient in fat-soluble vitamin. Very recently it has been suggested⁸ that

on rats, for in these animals fat-soluble vitamin has been entirely excluded from the food. Our dietary was devised from the standpoint of rendering the deficiency no more stringent than might occur under clinical conditions. In this respect it may be compared to diets we encounter in cases of infantile scurvy, which are never completely devoid of the antiscorbutic factor. It is quite possible, furthermore, that the rat is more sensitive to this deficiency disease than is man, just as man is far more sensitive than the rat to a lack of antiscorbutic vitamin.

CLINICAL REPORTS FROM JAPAN AND DENMARK

But let us turn to the clinical reports from Japan⁶ and from Denmark⁷ to see whether we can harmonize or correlate our results. The former tells us that the disorder occurred in the summer time in conjunction with diarrhea; that it rarely occurs in children under 1 year or in those over 15 years of age, and that the diet consisted of "rice, barley, cereals, beans and other vegetables." These vegetables are not specifically mentioned. The cure was remarkably prompt when cod liver oil was given, in some cases marked improvement being observed in half a day, results resembling the cures of beriberi in man or polyneuritis in pigeons. Further details are not given as to the quantity or the exact ingredients of the diet, of the length of time it was taken, nor as to whether any other change was made when the cod liver oil was given. Olive oil was ineffective. The data are so fragmentary that it is almost impossible to express an opinion on this report. Much would depend on the kind of vegetables that were eaten whether legumes or of the leafy variety. It seems very probable that the caloric content of the food was insufficient, and that it was lacking in an adequate supply of protein.

The Danish report is much fuller and gives us an account of forty-nine cases of eye trouble that occurred in Copenhagen from 1912 to the end of 1916. This publication of Bloch's, which is in the Danish language, has been cited so frequently to show the danger to

Chart 6.—Growth (minimal fat-soluble vitamin): Gain in length and weight (compared to the normal) of infants on the diet deficient in fat-soluble vitamin. This dietary led to no definite retardation.

many children may fail to grow normally because of an insufficient amount of this vitamin, which, compared to the water-soluble vitamin, is distributed so sparingly among the natural foodstuffs.

In view of these experiences and opinions, our infants were watched and examined with the greatest of care, and it will be well to report their condition in some detail. Their general appearance is decidedly good. One, about 2 years of age, who has been on the diet for the longest period, is up and about and has excellent color. The hemoglobin of the group averages between 80 and 90 per cent., and the red blood cells about 4,000,000 per cubic millimeter of blood. Their pulse, respiration and electrical reactions are normal. Roentgenograms of the heart show no changes, and of the bones shown no signs at the epiphyses resembling the lesions characteristic of rickets or of scurvy. Their growth in length has been normal, and their growth in weight slightly below the normal (Chart 6). In one case in which the gain had been slow, a larger amount of wheat cereal (cream of wheat) was given to note whether a food lacking in fat-soluble vitamin could bring about a gain. As will be seen in Chart 7, this addition of carbohydrate resulted in a prompt and definite rise in the weight curve. We may summarize our results by the statement that the only abnormal condition observed has been a mild retardation in gain in weight. How are these conclusions to be brought into harmony with the experimental and clinical results of others? It should be understood that this experience is not comparable to the feeding tests carried out

Chart 7.—Minimal fat-soluble diet; weight curve of one of the patients on a fat-soluble deficiency diet; evidence that gain can be brought about by adding cereal to the dietary without increasing the amount of fat-soluble vitamin; lack of gain therefore not due to the want of this growth factor.

infants of a deficiency of fat-soluble vitamin that it deserves careful reading and analysis. The infants were pale, flabby and very thin, with dry, scaly and shriveled skin. Of the forty-nine infants, twenty were between 6 and 12 months of age, fifteen from 2 to 6 months of age, and fourteen over 1 year. They suffered from what Bloch terms "psychic hyperesthesia," and would scream and twist and turn, and wanted to be let alone. The malnutrition was extreme in many

cases; for example, one baby of 9 months weighed 9 pounds, one of a year weighed 13½ pounds, another aged 2 years weighed 14 pounds. Their diet consisted of an indefinite amount of skimmed milk that had been pasteurized and cooked again in the home. Oatmeal gruel and barley soup constituted an important part of their dietary; one case is mentioned in which the baby had received nothing except oatmeal gruel and sugar. In no case were vegetables given, and in only one instance fruit juice, and then for only three days. A cure was obtained by means of cod liver oil, but in almost every instance breast milk or raw cow's milk was given in addition. It is very probable that some of this malnutrition was due to a lack of fat-soluble vitamin; it seems, however, equally true that other deficiencies played a more important rôle. These infants were partially starved and also received an insufficient allowance of antiscorbutic vitamin in the doubly heated milk. Scurvy is mentioned in only one instance, but in many others it must have been latent or subacute. It is therefore impossible to evaluate this report; it cannot, however, be used to illustrate the danger of fat-soluble vitamin deficiency. Animal experiments designed to elucidate this question would not be accepted if devised and carried out in this manner. What is true of this report will hold good of many of the nutritional experiences derived in the course of the war. The pictures are unavoidably confused and composite, rendering it most difficult to deduce valuable lessons from them. In most cases partial starvation is a basic factor, and infection plays a rôle. For example, the cases of scurvy reported from Austria—with large and numerous subcutaneous hemorrhages—resemble melena or purpura rather than true and uncomplicated scurvy. Similar conditions may occur in peace times. We have recently seen a group of infants who were suffering from a combination of deficiency diseases brought about by an insufficient caloric content of the food and a lack of antiscorbutic as well as of fat-soluble vitamin.

COMMENT

Our experience leads us to believe that except under exceptional circumstances—as in time of war—the danger to the infant and to the child from a deficiency of the fat-soluble factor is one not to cause great apprehension. It is true that this principle is by no means so widely distributed in nature as the water-soluble vitamin, but, on the other hand, infants seem able to thrive for long periods on very limited quantities, provided the diet is otherwise complete. The great danger arises from diets composed merely of cereal and water or perhaps an insufficient amount of buttermilk

or skimmed milk.⁹ It is probably true that a catastrophe will result if the incomplete diet is maintained for years, or even sooner in a susceptible individual, as is well known to be the case in scurvy or in beriberi. In formulating dietaries for infants and children, therefore, this food factor should be borne in mind and be regarded as an essential constituent.

There is a growing danger of attributing every unexplained growth impulse to the new, attractive but ill-defined vitamins—of their sharing with the secretions of the endocrine glands the fate of becoming the dumping-ground for every unidentified factor. It should be borne in mind that there are other little understood factors and food reactions. One of these is the peculiar and almost specific rôle that cereal plays in the nutrition of the infant. This phenomenon has been of especial interest to us for some time, and well illustrates the complexity of nutritional problems.

Not infrequently infants receiving diets which, according to accepted standards, should be adequate, fail to gain until cereal is given in addition. These babies usually are 6 months or more of age, and receive milk mixtures that should suffice to bring about growth. As the result of such experience, physicians add cereal to the milk diet when there is a failure to gain about the second half year of life. In order to obtain more precise information in regard to this interesting phenomenon, for which there is no satisfactory explanation, we studied a number of infants who had reached this stationary phase. It was found that in cases in which even cod liver oil no longer caused a gain, and in which egg yolk and beef drippings had failed, a small amount of wheat cereal (cream of wheat) brought about a decided increase (Chart 8). This result occurred whether the previous diet had been rich in fats, as just instanced, or contained a carbohydrate such as Mellin's Food

(maltose and dextrin, Chart 8). In one instance, when large amounts of autolyzed yeast failed to stimulate growth, the wheat cereal was effective (Chart 8.) Another, a breast-fed baby aged 8 months which had not gained for three weeks, increased 6 ounces as soon as a small amount of cereal was given in addition to the nursings. These gains could not be due to an addition of any of the recognized vitamins, as diets rich in the antiscorbutic, water-soluble and fat-soluble factors were nevertheless enhanced in value by the cereal addition. Nor could it be the result of a simple caloric increase in food, for

Chart 8.—Effect of cereal (cream of wheat, 2.5 gm., 17 calories) added to diet: four patients who had reached a stationary phase in weight; gains were brought about by small additions of cereal to a diet that was adequate in caloric content. The first three diets were unusually rich in fat-soluble and the fourth in water-soluble vitamin (autolyzed yeast). In the last case (J. H.) 4 gm. of dried cereal, equivalent to 28 calories of food, were added.

9. A favorite food for very young and premature infants is butter-milk or the "Holländische Säuglingsnahrung," which consists of butter-milk (with a fat content about the same as that of skimmed milk), sugar and flour. Babies may thrive on this food, deficient in fat, from birth until the second half year of life.

the amount added was comparatively insignificant. Cooked cereal equivalent to only 2 or 3 gm. of the dry cereal frequently led to a gain of 2 or 3 ounces by the following day. These babies were receiving a high caloric diet. In one instance a quart of protein milk and 30 c.c. of cod liver oil were given, representing about 120 calories per kilogram of body weight (Chart 8). The simplest and most direct explanation of this reaction is that this carbohydrate brings about a more complete oxidation and thereby a better utilization of the food. However this may be, it illustrates the point that not everything which induces growth—and which does not conform to accepted standards—is a vitamin.¹⁰

CONCLUSIONS

It would lead too far afield to discuss the various theories that have been advanced to account for the occurrence of rickets, and, moreover, it would not be profitable at the present time, as the data are inadequate. There seem to be several causes at work, rendering the unraveling of the problem so difficult that there is a difference of opinion not only as to the particular dietary factor that is at fault, but even as to whether rickets is to be considered a disorder of dietetic origin. It should not be lost sight of that there is a prenatal factor involved. The fact that the negro infant, living side by side with the white in the larger cities and obtaining milk from the same source, develops rickets so frequently and so markedly, indicates that there are important influences to be reckoned with in addition to the food.

In considering the diet a most important question is whether the recent theory as to the vitamin origin of this disorder can be maintained and, more particularly, whether rickets should be attributed to a lack of the fat-soluble factor. We can obtain the clearest understanding of this aspect by comparing this disease to the well recognized and established deficiency diseases, scurvy and beriberi. What does the comparison show? In the first place, these two disorders are commonly accompanied by weakness and malnutrition; we do not encounter the strong, apparently healthy babies met in rickets. But of far greater moment is the fact that neither can be brought about by overfeeding. Rickets, as emphasized in the body of this paper, frequently develops in infants receiving too much milk rich in fat, protein and salts. It seems impossible to bring this fact into consonance with a deficiency disease, whatever may be its nature, using this term in the commonly accepted sense. Our study shows that the fat-soluble vitamin is not the controlling influence; that infants develop rickets while receiving a full amount of this principle, and that they do not manifest signs, although deprived of this vitamin for many months, at the most vulnerable period of their life. It is impossible to interpret the contrary conclusion which Mellanby came to as the result of his pioneer experiments on dogs, or to accept the term "fat-soluble vitamin" as synonymous with "antirachitic factor," as Hopkins and Chick would have us do. Clinical tests carried out with care must be accorded fully as much weight as laboratory investigations. The two methods of approach should be carried out side by side, and even

the most thorough study on animals must be made to harmonize before it can be accepted as holding good for man.

Finally, this work seems to show that the danger to infants of a diet deficient in fat-soluble vitamin is slight, provided it includes sufficient calories, and otherwise is complete. They can maintain their health and vigor despite amounts of fat-soluble vitamin so small as rarely to be encountered in times of peace. In spite of the fact, therefore, that this vitamin is not widely distributed in nature, a disorder that may be termed "fat-soluble deficiency"—marasmus or xerophthalmia—is hardly to be apprehended from a clinical standpoint.

A CAMPAIGN AGAINST VENEREAL DISEASE IN THE ARMY OF OCCUPATION

DAVID M. DAVIS, M.D.

BALTIMORE

In the campaign against venereal disease, many measures which seem to give promise of good results are never tried on account of their impracticable nature in ordinary communities. During the occupation of a part of Germany by the United States Army, opportunity was given to test some of these measures, owing to the facts: first, that there were none of the ordinary legal obstacles now in the way; and second, that the army authorities were so deeply interested in keeping the venereal rate at a minimum that every facility for the work was made available.

This paper deals only with the means used and the results obtained in the Third Division during the first four months of the occupation.

During the summer of 1918, the Third Division had been almost constantly in action, making a splendid record for itself. Incidentally, an extremely low venereal rate had been maintained, as can be seen by reference to Table 1; and although it was felt that lack of exposure had had something to do with it, every one in the division was anxious to maintain the high standard in Germany.

The division started its march toward the Rhine from the vicinity of Bar-le-Duc on or about Nov. 16, 1918. From then until December 17, the troops were almost continuously on the move, and opportunities for exposure to venereal disease were almost as limited as during the period of battle. Division headquarters remained at Remich, Luxembourg, on the Moselle River, for several days just before December 1, and at this time, acting as division urologist, I submitted the following memorandum, which was an effort to foresee conditions as they would be after the occupying troops had settled down in their assigned areas:

The prostitution problem divides itself into two parts: (a) registered, and (b) clandestine prostitutes. From the police in Germany the names and addresses of all registered prostitutes can be obtained. They and the clandestines can be considered as operating: (1) on the streets; (2) in cafés, theaters and dance halls, and (3) in brothels. In order to cope with the situation, a definite policy must be laid down and followed. Should there be no army order on the subject, such a policy could with advantage be determined by a division order. The registered women are at once available. Shall they be interned, deported, or allowed to operate in

10. This phenomenon is similar to that reported from Hopkin's laboratory by Winfield (Report 116, Local Government Board, 1913, p. 147). It was found that rats failed to grow on a milk diet when they were one-half to two-thirds full grown, and that "the addition of fresh milk alone produced no acceleration of growth." "With a diet of bread and milk, growth recommenced." Ferric ammonium citrate and a preparation of hemoglobin were added without result.

brothels which are placed out of bounds? The last alternative has the objection that it always leads to abuses and evasions. The clandestines must be met by regulating the streets, cafés, theaters and dance halls. For the streets, rules similar to those in force at Bordeaux, forbidding soldiers and officers to appear in the company of women, might be enforced. Dance halls may be closed or put out of bounds. Theaters may be closed, put out of bounds or allowed to operate under supervision provided no women are permitted to loiter about in them. Cafés may be put out of bounds. In German cafés the waiters are usually women, these usually clandestine prostitutes.

The venereal problem in Germany will be one of the utmost importance for the welfare of the soldiers and the reputation of the Army. Stringent measures will be necessary to maintain the extremely low venereal rate of the A. E. F. A definite policy, clearly outlined and enforced from the beginning, will be of great assistance in the solving of the problem.

A third army order on the subject was not issued, so each division proceeded to solve its own problem along the lines already laid down by general headquarters after the recommendations of the senior consultant in urology, which had proved so successful in France.¹ This program was as applicable in Germany as in France, although certain conditions peculiar to the occupied area required decision, some of which made possible more effective measures than had been practicable in Allied territory. This being the case, it is remarkable to note how in each division, practically identical methods were arrived at sooner or later. Third Division headquarters were established at Andernach-am-Rhein, Kreis Mayen, Dec. 16, 1918. The area assigned to the division coincided almost exactly with the Kreis Mayen. This "Kreis" had a population variously estimated at from 50,000 to 80,000 people. There were two larger towns, Mayen, of about 10,000, and Andernach, of about 9,000 inhabitants, and approximately twenty-five small villages, all occupied nearly or quite to the limit, by the division troops. The men were practically all billeted in the houses of the inhabitants and other suitable buildings. In the dwellings, sufficient space for the family was set aside, and the rest of the house was occupied by soldiers. This, of course, brought the soldiers and Germans into close, and at times intimate contact.

The Kreis Mayen occupies an area in the Coblenz plain, facing the Rhine River, including principally the valley of the Nette River, and a good deal of high mountainous country around the Laacher See. It also extends far enough to the southeast to touch the Moselle River for some distance. In Andernach and Mayen are a number of factories, such as food canneries, iron works and breweries. Between these towns, on the volcanic strata emanating originally from the Laacher See volcano, are numerous establishments for the manufacture of cement, together with large quarries to supply the stone for these cement factories as well as for other purposes. The remainder of the Kreis is given over to agriculture, with a number of vineyards along the Moselle. Railways connect Andernach and Mayen, Mayen and Coblenz, Mayen and Munstermaifeld, and Mayen and the territory to the southwest. The main Coblenz-Cologne line runs along the Rhine border of the Kreis, and the main Coblenz-Treves line along the Moselle border.

From this short résumé it will be seen that the problem concerned a community about half agricultural and

half industrial, with two moderate sized towns, good railway connections, and lying from 15 to 25 kilometers from the city of Coblenz.

From the German officials it was learned that there were no registered prostitutes or recognized houses of prostitution in the Kreis. Amusement places were few and small, and the cafés also small and unpretentious, but numerous. During the war, many of the factories had been transformed for the manufacture of munitions. This had brought many girls to the towns to work in these factories, and had given them contact with the soldiers comprising the garrisons, and those working in the supply departments of the army. From German sources it was learned that while the district had been very free from venereal disease before and during the early stages of the war, the conditions described had brought about a notable increase during its last two years.

It will be noted that all of the prostitution to be combated was of the clandestine type. For this reason, none of the measures usual in the American Expeditionary Forces against houses of prostitution and segregated districts could be applied. The other parts of the program, however, were carried out as vigorously as possible. Prophylactic stations were established at every point occupied by soldiers. Prophylactic instruction at frequent intervals was insisted on, and line officers as well as medical officers took part in it. This included the customary admonition that continence was desirable from every point of view, statements of the nature and results of venereal disease, and a reminder that prophylaxis was insisted on to protect the innocent, not to encourage the guilty. Biweekly examinations for venereal disease were carefully made, the medical officers using complete company rosters and checking off by name so that no one escaped. The

sale of liquor was forbidden except between 5 and 7 p. m. Fraternization with Germans of either sex had been forbidden. The welfare organizations had comprehensive plans for the amusement of the men; but time was required to put them in operation. Meanwhile, a heavy drilling schedule kept the men busy during most of the few hours of daylight there were at that time of the year. Aside from closing one dance hall at Andernach, nothing further could be done except to await developments.

For nearly four weeks no case of venereal disease contracted in the occupied area came to light. Then a few cases were reported (Table 1). Questioning of

1. Bull. 54, General Headquarters, A. E. F. Young, H. H.: Preventive Medicine as Applied to Venereal and Skin Diseases, J. A. M. A. 73: 1668 (Nov. 29) 1919.

the infected soldiers and the activities of the military police and intelligence sections provided evidence against several women as being sources of infection. These women were apprehended and turned over to the German authorities for internment and treatment for a period of three months. A general policy for dealing with venereal disease was soon developed. It is desired to emphasize the fact that this policy was modeled after that used in handling other infectious diseases, and was based on the principle of quarantine. Infected women were to be isolated by the Germans,

and infected men were to be isolated by the American authorities until declared cured, according to the best criteria available. Details of the hospital treatment of infected soldiers will be given later. The Germans had no adequate system tending to regulate prostitution. The towns were too small to attract the registered prostitutes or have a morals police. Provision was made for the treatment in hospitals at public expense of women afflicted with venereal disease; but very few had availed themselves of this privilege. Women known to be prostitutes were required by law to report to the burgomaster once a week, but no effort was made to control them, and this measure was a "dead letter."

All of the hospitals in the occupied area were being utilized to a greater or less extent by the Army authorities, and therefore no treatment center was available for the women. The German authorities, who showed no inclination to cooperate, and no interest in the fate of these unfortunate women, were content to place them, for the period of their confinement, in the ordinary jails. No medical treatment was provided, although some of the women were in the secondary stage of syphilis; and they were crowded in the jails. As soon as this state of affairs was discovered, medical treatment was ordered, and supplied. This was done ungraciously, and in Andernach had to be hastened by the trial and punishment of the burgomaster. The Germans were also informed that better accommodations must be found. A certain amount of space was found to be still available in some of the hospitals; but this was insufficient for handling the increasing number of women. Through the hearty cooperation of the commanding general, the chief of staff and the division surgeon, steps were taken to evacuate completely a German hospital at Niedermendig, then occupied by American troops. Wooden barracks were built to accommodate these men. As soon as this was accomplished, the confinement and treatment of all women apprehended was carried out at this center under the direction of a competent local physician. The costs in each case were

borne by the village or town from which the woman came, according to a ruling of the landrat. General supervision was maintained by the American authorities, with whom rested the final decision as to noninfectiousness, and also the decision as to the parole of favorable cases.

The work of trying and ordering the confinement of infected women who had transmitted disease to or consorted with American soldiers was done by the inferior provost courts of the various localities. A clean cut case was required, and hearsay evidence, especially from German sources, was ruled out. It was found possible to apprehend over 50 per cent. of the women infecting soldiers, besides those taken in extemporized brothels, or elsewhere. All cases were reported at once to the division urologist and to the superior provost judge of the division. By frequent visits to the treatment center, it was possible to follow each case, and deal with it on its merits. In gonorrhea, three successive negative examinations constituted the criterion of noninfectiousness. In syphilis, patients were kept, even after the disappearance of lesions, until a thorough course of neoarsphenamin had been completed. When pronounced noninfectious, it was the general policy to parole all women who seemed to show an inclination to mend their ways. Others were held until the end of the period for which they were ordered confined, when, if still infectious, they were recommitted. Although well treated, well fed and well clothed in the hospital, all displayed the greatest anxiety to avoid a second sojourn there. Arrangements were made to confine in a German convent at Coblenz any incorrigible prostitutes who showed no evidence of disease. Only four cases fell in this class, and one woman succeeded in escaping and leaving the area before she was sent to the convent. One patient with disease, from a well-to-do family, was allowed to go to a hospital in a distant city for treatment, on her father's undertaking to be responsible for her safe-keeping. All the other patients were treated at the treatment center, and it was not necessary during my service in Germany to apprehend a woman the second time.

The Germans were indifferent, or even hostile, to this program. The prevalent ideas were quite medieval, and it was generally considered that a policy of public persecution would be preferable. They were indignant because the Americans required the treatment of these women in the best hospitals, and because the regular hospital diet and good treatment for them were insisted on. Many of the women, however, responded in a very gratifying way to this good treatment, and to the efforts made to bear out the statement that we were trying to help them lead a respectable existence in the future. There was also evidence to show that the fact that all cases were rigorously followed up served as an effective deterrent, many German girls avoiding the American soldiers altogether.

This policy, supported by the hearty cooperation of all concerned, enabled women of all classes to be apprehended. They included semiprostitutes, such as café waitresses and the inmates of hastily organized brothels, factory girls, shop girls, and women and girls living at home. A large majority were found to come from the industrial, rather than from the agricultural, sections. It provided prompt treatment for all, and, it is hoped, reformatory influence for some of these unfortunate women. It made possible the extermina-

tion of all extemporized houses of prostitution through the prompt internment of all the inmates. It may have served as an object lesson to the German population in what we think are more modern, more rational and more effective methods of dealing with prostitution and venereal disease.

All soldiers found with acute venereal disease, or chronic venereal disease in an infectious form, were sent at once from their units to a field hospital, established in suitable German buildings, where they were treated in the venereal ward without pass privileges. Standard methods of treatment were used. Cases with severe complications and all cases of fresh chancre had to be evacuated farther back. Three successive negative examinations of fluid expressed by prostatic massage constituted the criterion of noninfectiousness in gonorrhea. The men were all tried by court-martial, according to army regulations, and any confinement given as punishment had to be undergone after they had left the hospital. In this ward also neo-arsphen-amin treatment of all old chronic (noninfectious) syphilitics who could be discovered in the division was carried out.

The results of this campaign have to be estimated from the figures in the accompanying tables. Beginning in February, 1919, numbers of men went away, principally to France, on leave, and from these men came a considerable proportion of the cases of venereal disease. The only part of the campaign affecting this incidence was the prophylactic instruction. A large proportion of the men contracting disease on leave had failed to take prophylaxis for various reasons. Instruction was pushed very hard when this fact became known, printed posters being used freely to assist it. From the first half of March on, cases contracted on leave showed a gradual diminution throughout the Third Army, including the Third Division. In the occupied area, the number of cases contracted each week showed, after reaching its peak, a decline to a low figure. The total figures for the Third Army are lower than any ever previously reported elsewhere. It is not going too far to assign this good result to the energetic efforts made in the campaign which has been here described.

The effectiveness of the campaign is not ascribed to any one of the measures comprised in it. Throughout the American Expeditionary Forces it was shown that the problem was most effectively handled when every avenue of attack was utilized. Indeed, it seemed that each measure had a synergistic effect on the others used simultaneously with it; no doubt this was due to a conscious or subconscious effect on the mind of the individual soldier, who found an effort of the authorities, whenever he turned, to amuse and occupy him, to instruct him, to prevent his reaching prostitutes, to provide prophylaxis, to give him the best treatment in case all else failed to keep him from being infected, and to punish him for this infraction of discipline and public spirit. Every soldier, even the dullest, must have become aware at some time of the far-reaching schemes to take him home clean. It is at present impossible that such a campaign of quarantine could be made in a peace time community. Having been prosecuted, however, under such unusual conditions, its methods and results may well be of interest from a standpoint of social hygiene, since they show what can be accomplished when all elements of the problem are under control.

AORTITIS SYPHILITICA

C. F. HOOVER, M.D.

CLEVELAND

An editorial in a recent number of *THE JOURNAL* gives the impression that the diagnosis of aortitis is something very recent, and in practice rests on the development of subjective symptoms and the use of the roentgen ray and the Wassermann reaction. The following statement is made¹: "It seems highly probable that in the aorta; just as in the central nervous system, definite lesions may be present without any symptoms whatever, and it would seem that some method of diagnosing syphilitic aortitis during the pre-symptomatic period must be devised." Such a statement comes as a great surprise to clinicians whose professional career extends over the past three decades.

The diagnostic signs of aortitis were clearly described long before the roentgen ray or the Wassermann reaction or the spirochete was known to the medical profession. Physicians who knew and built on the work of Huchard² must certainly share in the writer's surprise over the statement that the "presymptomatic period of aortitis is still wanting a method of diagnosis." If inaccurate percussion and palpation and auscultation are employed, then of course the roentgen ray affords the only dependable diagnostic method; but in the hands of an examiner who in a routine manner estimates the size and elasticity of the ascending aorta, just as the character of the arterial pulse is studied, the presymptomatic period of aortitis is diagnosed with fully as much accuracy as can be procured by aid of the roentgen ray and Wassermann reaction. Fortunately for the recognition of early aortitis, the ascending or first portion of the arch shares in the process in fully 95 per cent. of the cases, and in the majority of cases the pathologic changes are confined to this portion of the arch. This discussion of the subject will be limited to the first or ascending portion of the arch.

If only the ascending arch is diseased, without accompanying mediastinitis or encroachment on the lumen of a coronary artery, the patient's capacity for exercise will not be impaired, there will be no subjective symptoms of any kind, and the volume of the pulse, the pulse pressure, and the characters of the anacrotus and catacrotus will be normal. What is vaguely described in the editorial as "so-called pulsatory plethora, namely, a marked pulsation of the peripheral vessels," implies a very advanced and extensive lesion of the aorta. Such symptoms are the capillary pulse, large pulse pressure, celerity in the catacrotus, and pistol-shot tone in the femoral artery. These cases were described by several writers years ago as cases of "pseudo-aortic insufficiency." There was nothing "pseudo" about it; they were cases of genuine insufficiency of the aorta, but not insufficiency of the aortic valve. The large pulse pressure and capillary pulse were simply evidences of the ventricle compensating for a loss of elasticity in the aortic tube; hence the systolic blush in the capillaries and relatively low minimum diastolic pressure, for which the heightened systolic pressure compensated. The pistol-shot tone was due to the sudden arrest of an exaggerated excursion of the arterial wall. The so-called "pulsatory plethora" was evidence of a severe and extensive lesion of the aorta.

1. Syphilitic Aortitis, editorial, *J. A. M. A.* 73: 1615 (Nov. 22) 1919.
2. Huchard: *Maladies du cœur et des vaisseaux*, Paris, 1889.

The important case, from the standpoint of a practicing physician, is the early one with slight or no subjective symptoms on the part of the patient. It is the lesion of the ascending aorta, that part of the aorta which is very accessible and susceptible to very accurate criticism so far as its size and elasticity are concerned. Such are the early cases of syphilitic aortitis, which respond well to treatment and for this reason should be recognized by the examining physician. If the diagnosis is not made until "pulsating plethora," angina from functional ischemia of the myocardium, and the broad silhouette from the roentgen ray constitute the diagnostic evidences, then the therapeutic opportunity is lost.

Elastic, fibrous and muscular tissues form the wall of the aorta. The smooth muscle fiber is, however, the constituent which enables the aortic wall to withstand intra-aortic pressure. When the muscle fiber deteriorates, the aortic tube is elongated and dilated. This increment in size need be very little to give unequivocal evidences to physical examination. On one occasion the pulsating aorta was clearly visible and palpable 4 cm. to the right of the sternum. The necropsy revealed that the entire ascending arch of the aorta had a uniform circumference of 11 cm., which means a diameter of 3.5 cm.—less than the distance to which the aorta extended to the right of the sternum. The projection of the aorta against the anterior thoracic wall to the right of the sternum was due more to its elongation than to its dilatation. It is elongation of the ascending arch and not dilatation which renders the aorta so readily accessible after slight pathologic changes.

ELONGATION AND DILATATION

Now, what physical signs will elongation of the ascending arch of the aorta give? The visibility of the aorta to the right of the sternum depends not only on elongation and dilatation of the aorta, but on the size of the thoracic cage and volume of the lung. With a given size of aorta, the patient with a chest of large anteroposterior diameter will afford less evidence of the enlargement of the aorta to the right of the sternum than will the patient who has a chest cavity of small anteroposterior diameter. As a rule, by the time the aortic pulsation is visible to the right of the sternum, one is dealing with a severe aortic disease, which requires no particular skill in diagnosis and offers little prospect for improvement with the employment of therapy. It is very important that slight degrees of enlargement of the aorta should be detected by the physician, because it is only in the early stages that therapeutic results are satisfactory.

Percussion for aortic dulness to the right of the sternum should be done by the direct palpating method. If one employs mediate percussion in this vicinity, the sternum and neighboring ribs are included in the pleximeter. If percussion is to be of a definitive character, and the examiner is to define accurately the limits of a resistant body behind the thoracic wall, then the method of percussion must be one which will employ the smallest possible pleximeter area, and this is best accomplished by employing direct percussion with the extended finger. As a matter of routine, the examiner should percuss the intercostal spaces to right and left of the sternum, beginning at the first intercostal space on the right and continuing downward to the fifth, and percussing downward from the first intercostal space on the left until precordial resistance is encountered, which is usually on the third rib. If the aortic arch

projects beyond the sternum at the second interspace, then the examiner will perceive increased resistance and diminished resonance in the second interspace to the right as compared with the second interspace to the left of the sternum; and comparisons should also be made between the resistance and resonance of the first, second and third interspaces to the right of the sternum. If this method of percussing is employed, the examiner will find that the projection of the aorta on the anterior thoracic wall, as determined by percussion, will not be inferior to the projection of the silhouette of the aorta as seen by the roentgen ray, and under some conditions the information gained by percussion is more dependable.

SYSTOLIC PULSATION OF THE ARCH

An increase in pulsatory expansion of the aorta during systole may be detected by palpating bimanually. The examiner places his right hand over the second interspace at the right of the sternum, and his left in the interscapular space at the left of the vertebrae. This method of palpation does not employ the tactile sense or vibratory sense of the palpating hand, but the muscular sense of the thoracoscaphular muscles. But the muscular sense of the muscles which lead from the head to the neck and shoulders is much more delicate than the muscular sense of the thoracoscaphular muscles, and for this reason I find it a very distinct advantage also to apply the ear over the second interspace to the right of the sternum. An expansile pulsation is very often perceived by this direct method of auscultation when by employing the hands the pulsation escapes detection. So if there is any reason to suspect an enlargement of the ascending or transverse or descending arch of the aorta, it is a good practice to auscult with the ear directly applied to the chest; and coincidentally with the audible sound the examiner will often perceive over the aortic area during systole an anteroposterior expansion which will be imperceptible to the palpating hands.

Further evidence of enlargement of the ascending arch of the aorta is accentuation of the aortic second sound and the palpable diastolic impact perceptible at the second interspace to the right of the sternum. Accentuation of the aortic second sound depends purely on accessibility of the aortic tube due to its proximity to the anterior thoracic wall. Accentuation or increase in the intensity of the aortic diastolic sound does not depend on intra-aortic pressure. High aortic pressures do not give an accentuated aortic second sound unless there is increased accessibility of the aortic tube on account of elongation and dilatation of the aorta. When accentuation of the aortic second sound accompanies high aortic pressure, the accentuation is due to disease of the aorta and not to high pressure. If the first portion of the arch is elongated and dilated, the systolic pressure may be elevated or normal, but in either case we shall have accentuation of the aortic second sound in the second interspace to the right of the sternum. This accentuation means just one thing—increased accessibility of the first portion of the arch of the aorta.

We have very good contributory proof of this fact when there is traction of a normal aorta toward the right side due to retraction of the upper right lobe of the lung from chronic disease, as in fibroid phthisis. Under these conditions the aorta is displaced to the right by the receding right lobe, and the retraction of the upper right lobe of the lung also uncovers the arch

of the aorta. Under such circumstances, with a normal aorta and normal blood pressure, the aortic second sound will be greatly accentuated, and the accentuated sound may have exactly the same character as is frequently found in aortitis of the ascending arch.

PALPABILITY OF DIASTOLIC IMPACT

A palpable diastolic impact over the second interspace to the right of the sternum is perceptible in the adult only when there is increased accessibility of the arch. The diastolic impact is due to the arrest of a body in motion, and the body in motion is the column of blood within the aortic tube arrested by the closure of the aortic valve. This impact is transmitted as a vibration along the aortic wall to the examining hand.

The diastolic impact, I have observed, is best perceived by the part of the hand where vibratory sense is most acute, and that is over the end of the metacarpal bones. If one will apply a vibrating tuning fork over the finger tips and then over the ends of the metacarpal bones, it will be observed that the perception of vibration is much more acute over the ends of the metacarpals. One detects a diastolic impact through a sensory percept, which has been named pallesthesia, and it is very clearly differentiated from tactile sense and muscular sense. Correct palpation is very important. If the examiner will place himself at the right side of the patient and palpate the second interspace to the right of the sternum with the ends of the metacarpals, asking the patient to expire so as to render the aorta as accessible as possible, it will be found that only very slight dilatation of the arch of the aorta is required to make a diastolic impact clearly perceptible to the palpating hand.

LOSS OF ELASTICITY

Elasticity of the arch of the aorta greatly economizes the work of the heart in maintaining the minute volume flow of blood. Were the aorta not elastic, then the pulse would outlast the systole of the ventricle, for the duration of the pulse beyond the end of ventricular systole is due purely to aortic contraction. Should the aorta lose its elasticity, to compensate for the short duration of the pulse we should have a maximum systolic rise both in volume and in pressure, and a consequent lowering of the minimum diastolic pressure; but this modification of the pulse occurs only when the elasticity of the entire aorta is impaired, or at least when a very large portion of the aorta is involved. These are the severe cases which in former years were discussed in medical literature as pseudo-aortic insufficiency.

In this discussion I am dealing solely with elongation and dilatation of the first portion of the arch of the aorta, and that may be seriously diseased without modification of the pulse pressure or the duration of the arterial pulse. There is no physical sign ascribable to a loss of elasticity of the first portion of the arch of the aorta unless the root of the aorta is involved; and when the aortic ring and the first portion of the arch are diseased, the diastolic sound takes on a tympanitic quality. Now, an aortic second sound may be decidedly tympanitic and not accentuated, and this will occur when the root of the aorta is sclerosed and the aorta is not elongated and dilated. On the other hand, it is very common to find an accentuated second sound which is not tympanitic; and this will occur when the root of the aorta is not sclerotic, but when the remaining portion of the ascending arch is elongated and

dilated. I have been able to confirm both these statements by pathologic examinations. Furthermore, the tympanitic quality of the diastolic sound is not at all dependent on the height of the aortic pressure. On one occasion I had a patient under observation who was subject to periods of arterial hypertonus. For about three days in the week the man would have a maximum systolic pressure of 350, and then there would follow an interim of three or four days in which the maximum systolic pressure would be only 150. The only way in which one could detect the rise in arterial pressure was by palpating the femoral artery and using the blood pressure apparatus. This patient had no enlargement of his heart and no enlargement of his aorta. During the periods of high blood pressure, the aortic second sound was not palpable, and the increase in its intensity was very slight and certainly would have escaped observation had I not been making comparative observations on the intensity and duration of sound during periods of hypertonus and interims of normal pressure. Furthermore, the aortic second sound during the periods of high blood pressure had not the least suggestion of a tympanitic quality.

MURMURS

A murmur during the cardiac systole is audible over the second interspace at the right of the sternum when the ascending arch of the aorta is dilated, and also when there is stenosis of the orifice without dilatation of the arch of the aorta. The mechanism of production of this murmur is identical in both instances. The murmur is produced by eddies in the blood stream due to the passage of a column of fluid from a vessel of smaller to one of a larger lumen. Stenosis at the orifice and dilatation of the aorta directly beyond the orifice supply these conditions. But there are other factors besides relative stenosis which are necessary for the production of a murmur. The murmur will depend not only on change in the lumen of the tube, but also on the conformation of the tube where transition occurs from a smaller to a larger lumen. When the change is very abrupt, as seen in instances of a rigid valve projecting like a diaphragm into an aortic lumen, the murmur will be very loud, and so may it be quite loud when there is an abrupt dilatation of the aorta beyond the orifice. But suppose the aortic ring is normal, the root is not dilated, and there is a moderate fusiform enlargement of the ascending arch as it joins the transverse arch; then there will be no systolic murmur because this conformation does not give sufficient velocity to the eddies within the stream which are responsible for audible sounds commonly described as murmurs. Should there be fusiform enlargement or the ascending arch of the aorta as it joins the transverse arch, one should be able to percuss an area of dulness to the right of the sternum, one should palpate a systolic impulse when the ear is applied to the thoracic wall, and one should palpate a diastolic impact and hear an accentuation of the aortic second sound; but the aortic second sound will not be tympanitic in quality, and one may hear no murmur during cardiac systole. Should the ascending arch and the root of the aorta be sclerosed but the valves remain competent, then there would be present the physical conditions essential for the production of a systolic murmur and a tympanitic aortic second sound; but the intensity of the sound and the palpability of the diastolic impact and the systolic impulse would all depend on the dilatation of the arch of the aorta beyond its origin.

DISEASE OF THE CORONARY ARTERIES

Diagnosis of disease of the coronary arteries is not made by direct examination, but inferentially, by the history one is able to procure from the patient. When the coronary arteries are involved in syphilitic patients, they commonly give a history of progressive functional ischemia, and, of course, the cases which do not respond to treatment may go on to nutritive ischemia with all its consequences—infarcts and myomalacia cordis. Early in the patient's coronary history he finds he has lost the ability to perform vigorous exercise, and gradually his exercise will be cut down, so that moderate walking on level ground will be sufficient to bring on myocardial pain. In the early stages of syphilitic disease of the coronary artery, when therapeutic measures are of value, the diagnosis of coronary disease is based on a patient's history and his ability to exercise and not on any direct physical findings.

MEDIASTITIS

Syphilitic mediastinitis is a common accompaniment of syphilitic disease of the aortic wall. Substernal pain, inclusion of the laryngeal nerve, paroxysmal tachypnea, and pain on swallowing have all been observed. The only direct physical sign of syphilitic mediastinitis, quite apart from functional disturbances, is the location of a friction sound audible at the second interspace to the right of the sternum. In the few instances which have come under my observation, the friction was audible during cardiac diastole and followed the aortic diastolic sound. Disease of the coronary arteries and mediastinitis may occur when the disease of the aorta is not severe, and, in fact, when the aorta shows no evidences of modification in size or elasticity; and under these conditions, of course, the diagnosis is based on the impairment in function.

The diagnosis of aortitis based on physical findings, as described above, is very frequently made before the patient complains of symptoms which can in any way be ascribed to the heart or aorta. The therapeutic importance of making the diagnosis early is due to the fact that, if the physical signs are recognized soon enough, the use of adequate mercuric therapy will cause all of them to disappear. I have seen all the physical signs described above as traceable to enlargement of the arch of the aorta and to impaired elasticity disappear entirely under vigorous antisiphilitic therapy. When the disease has progressed to aneurysmal dilatation, or to the point at which diagnostic skill is no longer required to make the diagnosis, then therapeutic endeavors are in vain, so far as restoration of function is concerned, though it seems very probable that the progress of the disease may be arrested and the patient's life greatly prolonged when restoration to functional and anatomic integrity is no longer expected. Recovery from the evidence of sclerosis of the first portion of the arch of the aorta occurs only when the diagnosis is made quite early in the disease.

Contrary to the import of the editorial comment cited,¹ the medical profession does recognize its moral responsibility in making an early diagnosis of syphilitic aortitis. The early recognition of the lesion is due to the work of Fournier and Huchard, and is based on physical examination. It is very doubtful if men who followed the work of these great Frenchmen found themselves making the diagnosis of incipient syphilitic aortitis with any greater frequency after the roentgen ray and Wassermann reaction were added to our diagnostic resources than was the case prior to introduction

of these diagnostic aids. The Wassermann reaction, *Spirochæta pallida*, and the roentgen ray have all served to confirm and illuminate the work of these great clinicians, but bacteriology and pathology lagged many years behind the clinic in dealing cogently with syphilitic aortitis.

THE LABORATORY PROFESSOR AND
THE MEDICAL SCIENCES IN
THE UNITED STATES

CHARLES R. STOCKARD, M.S., PH.D.

Professor of Anatomy, Cornell University Medical College; Associate, Huntington Fund for Cancer Research; Consulting Anatomist, Clinic for Functional Reeducation of Disabled Soldiers, Sailors and Civilians; Consultant, St. Bartholomew's Hospital for Diseases of the Alimentary Canal

NEW YORK

In a recent number of *THE JOURNAL*, Professor Symmers¹ combined a discussion of the defects in the teaching of pathology, and the deficiencies of the "lay professor." The first portion of the article was devoted largely to the difficulties in obtaining pathologic material. In conclusion, however, the front was shifted and a still wider problem in medical education was briefly touched on. Dr. Symmers has, I believe, placed two eggs of quite different variety in the same nest. Neither may hatch a bird of beautiful plumage, yet there is little relationship between the two except that they were to be incubated by the heat of a single discussion. Doubtless the subjects are worthy of treatment apart.

I shall not ask the reader's indulgence on the subject of pathologic material for teaching, although ten years' experience in collecting anatomic material in the varying control of New York City leads one to feel that it would not be difficult to warm up to a sparkling degree on such a theme. My attention shall be limited entirely to the problems and conditions underlying the question of the "lay professor."

It should be understood that what I present is intended not solely as a reply to Dr. Symmers' brief treatment of this matter, but as an expansion or broader consideration of a condition which is of grave importance to medical education in the United States. The consideration should be as nearly unbiased as possible, since it is a question not of the welfare of individuals, but one of medical instruction and progress in a great country during a season of most rapid changes and developments.

There are objections to the expression "lay professor" since, in spite of its being apparently clever, it is not actually clear. It immediately introduces partisanship and prejudice into a case which in the end must stand on its merits alone. Judging from Professor Symmers' text, he would put outside of the profession anyone who had not followed the routine road of the medical curriculum in order to enter that branch of the profession to which he intended devoting his life's effort. This is in spite of the fact that the men of scientific education in the laboratories have often spent more time in their preliminary training, which always necessitates the completion of the college course, and in obtaining their doctorate, than the medical student need do. The time element is not of great importance; but men so trained would under Dr. Symmers' classification still be outside in spite of the value

1. Symmers, Douglas: Defects in the Teaching of Pathology, and the Lay Professor, *J. A. M. A.* 73:1651 (Nov. 29) 1919.

of their contributions to medical progress and practice. The profession would be limited to those having the legal status to practice it. To appreciate the full meaning of such a classification, may we look briefly at the recent medical past.

CONTRIBUTORS TO MEDICAL SCIENCE

A figure at once towers above all the rest, the son of a French tanner, a chemist by education and training, the father of bacteriology, the discoverer of the effective method of combating infectious diseases, he who disproved the idea of spontaneous generation, and laid the scientific basis for Lord Lister's aseptic surgery: Could anyone have so little regard for the history of medicine as not to include Louis Pasteur, the trained chemist, among the great leaders of the profession?

The phagocytic action of wandering cells in the animal body was discovered by a zoologist as a result of his earlier studies on the lowest invertebrates. When a young man he left his professorship of zoology at the University of St. Petersburg and spent his life in the Institut Pasteur constantly investigating the reactions of the organism to disease. Certainly few could deny that medicine is proud to claim the numerous contributions of that devoted investigator, Eli Metchnikoff.

Every medical man looks with pride on the record of the young zoologist who first stained and demonstrated the spirochete of syphilis after others had sought for years in vain. The investigations of the same man on the ameba of dysentery, and his final courage in sacrificing himself in order to facilitate such investigations when he was little more than 35, make all students of disease salute so noble a student as Fritz Schaudinn. A long list of other scientific men, without a medical degree, in Europe as well as in our own country, could readily be mentioned who have contributed most important discoveries as aids to diagnosis and the control of disease.

On the other hand, many of the great discoveries in medicine, as well as in pure science, have come from the medical men themselves, Harvey, Huxley, Haeckel, Ehrlich, and in our own country, Smith, Gorgas, Russell and others. But practical medicine, as well as other applied sciences, can ill afford to separate itself from the indispensable aid which the pure scientists in the laboratories have to supply. The primary thing to be kept in mind is, that when the laboratory man is a master in his field it matters not what his training may have been, whether medical or otherwise; he fully values and appreciates the bearing of his science in all its applications. As Pasteur stated it, "There is no greater charm for the investigator than to make new discoveries; but his pleasure is heightened when he sees that they have a direct application to practical life." Huxley estimated that the money value of Pasteur's discoveries on anthrax alone saved the world in sheep and oxen enough to cover the whole cost of the war indemnity paid by France to Germany in 1870.

In order to appreciate more fully what any applied science may expect to receive from the laity, we might look still further back in medical history. Out of the long record of *materia medica* there have come two so-called specific drugs for the treatment of disease. One of these, quinin, was discovered by savage laymen, the Indians of South America, while the exact credit for the discovery of mercury in the treatment of syphilis is difficult to place, but belongs to the profession. The race for the discovery of specific treatments after about 2,000 years of medical practice ends in a tie

between the Indians of South America and the physicians of Europe.

Among the long used drugs of vegetable origin, valuable in the relief of disease, the laity had in their possession digitalis, nux vomica, opium and many more. Modern medicine is further aided in the use of many of these substances on account of the fact that their active constituents have been separated by the "lay" chemist in concentrated form.

One of the earliest and most important steps toward putting medicine on a scientific basis took place about 150 years ago when the celebrated Englishman, Jenner, then a young man not yet in the medical school and without a medical degree, was told by a Gloucestershire milkmaid that one could not have the disease smallpox after having had cowpox. Jenner found this opinion to be commonly held by the people of the county, and told a number of physicians about it. None of them at that time were interested in such knowledge. While Jenner was studying in London he lived two years in the house of John Hunter, and communicated to him this peculiar relationship between cowpox and smallpox; but Hunter was also apparently not interested, being absorbed in his own work. Jenner, however, was born with the creative temperament. He was a musician, wrote poetry, and was a keenly observing naturalist as shown by his studies of the hibernation of the hedgehog, and the habits of the cuckoo. The last study was communicated to the Royal Society. With true scientific inclinations he returned to Gloucestershire after having studied in London and began the first experimental work on immunity. The actual discovery was made by the milkmaids of Gloucestershire, but its meaning was appreciated by the young apprentice, Jenner, years before Dr. Jenner devised the method of vaccination which made it unnecessary to lead the person to the cow. And thus the history of medicine progresses, until today it is the proud recipient on which is bestowed electricity, the roentgen ray, radium, etc.

Two kinds of minds are valuable or really indispensable to medicine: one the discoverer, and it matters not who or where he may be; the other, the one who comprehends the significance of things. The latter is often rarer than the former; many knew what the milkmaids said about smallpox, but only Jenner appreciated its value; and in so doing he became one of the landmarks in the progress of civilization.

A subject becomes scientific when it has advanced to a stage at which its study depends on exact experiment. Physics and chemistry long ago arrived at this point, and biology has been developing on such a basis for more than thirty years. These are the fundamental sciences on which medicine must progress. They have already supplied a splendid foundation. Much of it was built by the professional physicist, chemist and biologist; the practitioner of medicine in many cases has comprehended the worth of the discovery and devised the technic by which it was applied to the treatment of disease. Has either party to the contract actually suffered from the shortcomings of the other? Should the two be divorced, or are either to be considered "lay" by the other? Only one answer is possible: Does the trained engineer teach the fundamentals of physics and chemistry to the engineering student or does the physicist and chemist? The latter; and with elementary scientific knowledge the young engineer builds with a better understanding of forces and materials.

PROGRESS OF MEDICAL EDUCATION IN THE
UNITED STATES

With this fragmentary review of the parts played by extrinsic elements in the general growth of medicine, we may proceed to a consideration of the development of medical education in the United States which has led to the present conditions in American medical colleges. And finally an attempt will be made to suggest methods for the future improvement of the situation.

As late as the seventh and eighth decades of the last century it might be said almost without exaggeration that there were no actual working laboratories in the medical colleges of this country. There were only the smallest number of medical men devoting their time and talent to investigations in the fundamental medical sciences. In Europe, on the contrary, there were valuable investigations under way in almost every country, and the medical courses were in many universities already well arranged on an orderly scientific basis. One need only recall the purely scientific work being done by Huxley and other medical men in England.

In France, Pasteur was influencing the medical profession, and in Germany and Austria there were chemists, morphologists, physiologists and pathologists of historical prominence. While in this country there was no professional anatomist, zoology was just being born as a result of the arrival at Harvard of the Swiss naturalist, Louis Agassiz. Physiology was soon to begin on the return of young Bowditch from studies abroad. Chemistry in the medical college was taught by lectures and exhibits, or was included in the course of *materia medica*. Embryology was unknown to American medical men, who had not appreciated the simple necessity of understanding how the machine is built in order best to repair it. The essential apparatus for the study of histology was thought to be unnecessary extravagance, and pathology in its effort to arise labored under similar handicaps. The dissection of the human body was attempted on material either in a state of decay or mummified by medieval methods of embalming. This was of little consequence, however, since the actual knowledge of the subject was always to be harvested from that perpetual source of supply, Gray's textbook.

These and many other primitive conditions obtained when our fathers, and actually when some of us, wandered through that garden of knowledge then known as the medical curriculum. My own sire regrets the distinction of having obtained the degree of Doctor of Medicine from the University of Virginia after a single year's effort. Experiencing, however, a slight sense of hesitation in applying his knowledge to healing the sick, he came to New York and attended what many at that time considered the leading medical school of the country. After another year at the feet of pedantic preceptors he was again honored with the diploma of Doctor of Medicine. Such an experience even at that date was uniquely American. Another of my paternal relatives traveled to Vienna in order to obtain work in pathology which was then almost unobtainable in any form in this country. Many men of these schools are occasionally heard to criticize the modern course, since it does not begin at once by introducing the student to the clinic as in their day. They forget momentarily that in those good days there was little alternative to a start in the clinic.

After 1890, conditions took a decided turn and a rapid improvement began, due, in some degree at least, to the influence of a number of men who had studied

abroad and become acquainted with the vastly superior state of affairs in the medical schools of Europe. Interest was at once developed in the fundamental medical sciences, and the necessity of greater knowledge and longer training was realized as qualifications for a successful career in the battle with disease.

The advance in scientific medicine based on the discoveries of vaccines and antitoxins made a better education of the physician not only necessary for the intelligent application of such treatments, but really essential for any one aspiring to add to the knowledge or discovery of similar remedies. Preventive medicine was born, but refused to grow in size, or develop in power, on nourishment other than studious effort and thoroughly scientific understanding.

This state of affairs came as a shock to many physicians and surgeons who had up to this late time combined with apparent success a daily practice of their profession with a professorship of anatomy, physiology or pathology. A few boasted of having filled one after another of these chairs on the road to their ultimate ambition, the professorship of medicine or surgery. Others taught a cluster of subjects—*anatomy, physiology, etc.*—and as Oliver Wendell Holmes expressed it, "he occupied not a chair at Harvard but a settee."

It now became evident, with some persuasion from the outside in certain instances, that the fundamental sciences on which medicine was to live and advance must be properly included and taught in the curriculum. *Where were the teachers and investigators in these sciences to come from?* The medical men of the country graduating before 1890 had not in all cases been sufficiently trained in the medical sciences to qualify them to teach and work in these subjects. At the same time, many prominent physicians and surgeons could not afford to sacrifice their professional practice. *The simple fact was that there were but few men trained in the medical schools available for these laboratory positions.* When one contemplates the schools of that time, how could there have been many such men? And this was the day that the call went out from the medical colleges to the universities of America for a supply of professional chemists, physiologists and morphologists to train the medical student in the sciences which must underlie the modern prevention and cure of disease.

Many men had been trained in the pure science departments of the universities, and as a matter of information, some of these had gone for their education to the universities solely on account of the fact that laboratory training was not then to be had in the medical schools. Many of these men with natural interests and inclinations toward the medical sciences responded to this opportunity to work in the medical colleges. They did not intrude themselves or come into these positions because there were no others to be had, but were invited, and entered solely through preference for the work and their interest in medical science. I know instances of chemists, physiologists and morphologists having had invitations which gave them the opportunity to choose between professorships in the universities or the medical college, with the salary equally short in both cases, but they chose the medical college. I know other examples of laboratory professors in medical schools having gone to chairs in the university. And I have known of one such case in which the medical college later urged the professor to come back to its department; but the invitation was declined. Men of ability usually choose the atmosphere in which they work most effectively.

At the present time the number of scientifically trained men in the medical laboratories is unusually large, and their record as contributors and teachers is far from discouraging. The American Association of Anatomists counts among its members the full time men of professorial rank in almost every department of anatomy in the United States. Of the full professors of anatomy there are forty-five with a medical school education, and twenty-seven have been educated in the universities. Among the professors with the degree of M.D., thirty-five are directors or heads of anatomic departments, while twenty-one of the non-medical professors likewise head departments. In this country there are seventeen assistant and associate professors of anatomy with the M.D. degree, and twenty-four men of similar rank who are doctors of philosophy or science. Therefore, of the professional anatomists, sixty-two have gone into the subject after receiving the medical degree, but only the smaller percentage of these have served as hospital intern or had any clinical experience other than that obtained during the last year of the medical course. The same, in general, is true of the European anatomists. As Dr. Symmers mentions, Guy's Hospital requires the anatomist to have passed the examination for a fellowship in the College of Surgeons. It must be known, however, that this is simply another examination: the candidate need never have served in a hospital or had clinical experience. I have met men studying on the continent for their fellowship examination, and it is largely a matter of cramming much like our state board and hospital examinations. The fellowship is sometimes taken by a chemist working in the laboratory merely to obtain the letters F.R.C.S., which mean much to some people.

After the medical graduate becomes a professional anatomist, his time and efforts are so completely devoted to the difficult task of learning the subject and problems of morphology, and the teaching of students, that interest in the practical aspects of medicine other than its educational phases is soon lost. It has been said in this country that the teaching of medicine is not a medical problem but an educational problem.

Fifty-one professional anatomists have received their morphologic training in the universities, and have developed an appreciation of the medical and surgical aspects of the subject through a contact with the clinics after becoming associated with the medical school.

In considering the members of the American Physiological Society, it is found that honors are equally divided as to the number of full professors from the medical school and scientific school groups. There are twenty-three professors of physiology with the M.D. degree, and twenty-three with either the Ph.D. or D.Sc. Of the assistant professors, ten have the M.D. degree and thirteen do not. Three of the professors of physiology, who were not educated in the medical schools, have filled with distinction the position of dean of three leading medical colleges, Johns Hopkins, Minnesota and Virginia.

The Bio-Chemical Society shows only three full professors and one assistant professor of chemistry in medical schools with the M.D. degree. There are twenty-two full professors and twelve assistant professors of chemistry with Ph.D. degrees in the medical colleges. The chemists are derived almost entirely from the scientific departments of the universities, and yet their recent contributions to the chemistry of metabolism and to exact medical diagnosis have been of the utmost importance. One of these Ph.D. pro-

fessors of chemistry has recently filled the office of dean of Washington University Medical College most successfully.

In pharmacology the conditions are reversed, there being sixteen full professors and eleven assistant professors with the M.D. degree, and only four full professors without the M.D. degree. It would be unnecessary to compare the recent accomplishments of pharmacology with those of biochemistry.

The numbers of professors in physiology and chemistry are seen to be fewer than in anatomy on account of two facts: In the first place, in departments of anatomy the courses in gross and microscopic anatomy are frequently each in charge of a full professor or at least of an assistant professor. The second reason for low numbers in physiology and chemistry is that in some of the smaller schools the two subjects are taught under the direction of one professor. There are still a few settees among the furniture of the faculty room in the medical schools. In some cases this is due to lack of men, but more often to lack of money.

Finally, on a percentage basis the men of professorial rank with the M.D. degree are thus distributed in the different medical laboratories: Of anatomists, those having the M.D. degree constitute 55 per cent., of the physiologists 48 per cent. and of the medical chemists only 10 per cent.

All of the head pathologists have the M.D. degree, yet many of the pathologic laboratories contain, among their staff, men without the medical degree. Several leading professors of bacteriology in the medical colleges have had their initial training in the scientific schools and do not have the degree of M.D.

These different percentages of doctors of medicine in the various laboratories indicate that the earlier in the medical course a subject is given, and the less that subject is taught in the clinical years, the more surely will the student fail to develop a lasting interest, and never come back as a laboratory worker in the subject. At present, chemistry is taken earlier in the course and is less used in the instruction by the general clinician than the other laboratory subjects. Thus few, if any, doctors of medicine come back into the chemical laboratory. Even in England many of the leading physiologic chemists have not taken the medical course. A number of these men are of international distinction—Plimmer, Hopkins, Bayliss, Schryver, Armstrong, Harden, Dakin, Barger and others. Physiology is considerably more used and reviewed in the later years of the course, and so more medical men are found in this laboratory. Anatomic knowledge is employed still more throughout the course, and more than half of the professors have the medical degree. Pathology, being the science of disease, is available only in the medical college, and is used throughout the curriculum. Here, as one would expect, all of the heads of departments have the M.D. degree; but several of these have also worked in the scientific schools for a university degree. As the clinical instruction throughout the country becomes more and more scientific, and involves still more physiologic knowledge and more chemistry, the attraction of these subjects for the medical student will no doubt improve.

At present we see, therefore, a considerable proportion of men trained in the fundamental sciences working in the laboratories of the medical colleges. Do these scientists have a sympathetic appreciation of the medical situation, and do they obtain a knowledge of actual medical or clinical problems? They do, in the

case of those worthy of their hire. The M.D. graduate shows that he has an interest in medicine by having come to the medical college to study. In the case of choosing for a professorship between two men of equal ability, the preference should be, and is, always given to the M.D. by the medical college.

TRUE SITUATION IN THE SCHOOLS

It may be well just here to consider some of Dr. Symmers' statements of the situation in medical colleges in the light of the foregoing review. He says: "There are schools in this country in which the teaching in physiology and of physiologic chemistry is entrusted to men who have received no systematic training in medicine." This is correct, but does not quite convey the idea that in almost all medical colleges physiologic chemistry is taught by such men, and that half of the departments of physiology are under their direction. If we depended on medical graduates it would be impossible to teach chemistry in the medical colleges, and half of the departments of physiology would find it difficult to obtain a suitable director. Has the physiology taught and contributed by Howell at Johns Hopkins and Lusk at Yale and in New York been less useful to medical students than that taught by any two men that have passed through a medical course in this country? Has the work in biochemistry of Mendel, Folin, Benedict or Van Slyke been inferior to that of one or four men with medical degrees? Who contributes the textbooks of physiology and biochemistry most used by the medical students in the leading colleges of this country? The same texts are frequently used in the medical schools abroad, and some have been translated into continental languages.

To quote again: "There are at least two representative schools in this country in which the chair of anatomy is filled by men neither of whom holds a degree in medicine." This does not fully describe the situation, since there are twenty-one heads of anatomy departments who do not have a medical degree, and thirty-nine who have. Only very few of the thirty-nine did more than finish the last year of medical college, so that they have had no hospital or clinical experience other than that obtained in the medical course. Dr. Symmers fears that the anatomist without the medical degree is too short-sighted an individual to be able to enliven his course by constant reference to points of surgical value. Old songs all have a mellow tune! Eighteen or twenty years ago by no means all of the medical colleges in this country had professional anatomists teaching the subject; to put it gently, they understood little anatomy. Thus, some physicians still have dim recollections of surgical points learned in the anatomy class. They might realize, however, that they failed to receive a conception or an understanding of the principles of development and structure which enter into the make-up of the human body. These principles of structure have an important medical as well as surgical value. The good mechanic must not only understand the structure of his machine but should know how it is built and what each part does. The human body deserves at least such knowledge of its parts. In teaching the anatomy of fractures and dislocations to thirteen classes of military surgeons, I found them all to realize that the same knowledge of anatomy was involved after the fracture or dislocation as before. As a fact, it isn't any more the surgical points of value than the anatomic points of value, when properly given, which enliven the course. The study of living models,

which should begin on the first day, brings real life and interpretation into the modern anatomic course. It is probably best for the anatomists to teach anatomy and the surgeons surgery. Every one forgets the details, but the fundamentals of a subject are the laws which live in the mind of him who has known.

The teaching of embryology, Dr. Symmers says, "is commonly left to instructors few, if any, of whom are capable of vitalizing the intimacy between it and pathology, notably in the vast domain of tumors." Reversing the idea, the embryologist is often impressed by the inability of the pathologist to give logical interpretations, on account of a lack of first hand knowledge of embryology. Embryology is one subject that must be studied first hand in order to use it in deductive reasoning. There is a surprising number of able embryologists of international reputation teaching in American medical colleges, and Minot and Mall were their leaders.

"The teaching of histology is all too often entrusted to an assistant with the alphabetical distinction of a bachelor's degree in arts or science." This is a mistake in either the place or the time, as today in the United States a professor with one or two doctor's degrees generally gives the histology course.

How could any intelligent person, trained as a scientific investigator, camp for many years within the walls of a medical college, teaching a basic medical subject to students as well as doctors of medicine, without knowing what the problems of medicine and surgery must be? How could a medical student gather in so much during the last year or two of the course, that is, on supposition, beyond the grasp of the scientifically trained men who taught him during the previous two years? It should be comprehended that these laboratory men may learn first hand without a teacher. Every medical man does the same. Some students actually learn in spite of a teacher. The one great defect in the general school system as well as in the medical college is that the student is so rarely expected to learn for himself, he must be taught and too often from books. After all, however, it takes very simple mathematics to prove that the world would stand dead still but for the fact that each generation of students knows more than its teachers. This little *more* they learned for themselves, and this is the degree to which the generations push the world forward.

It must be realized that the men with the M.D. degree coming into the laboratories quickly lose touch with the clinical aspect of things in their effort to master and do creative work in the laboratory branch of their choice, while, on the other hand, the scientific man comes into the medical laboratory after being trained in his particular subject, and his effort for the first number of years is to acquaint himself with the medical bearing of things. Almost all such men that I know have studied general pathology and have attended systematically medical and surgical clinics for longer or shorter times.

Why is there this periodic excitement on the part of some clinicians and occasionally a pathologist, such as my friend Dr. Symmers, regarding the dangers to medical teaching and practice that might come from these men educated in the scientific schools? There is not an instance in history, so far as I have been able to gather, in which any harm has been done, and yet men of such training have worked in medicine for quite a long while in all the civilized countries of the world. The men who have aided in the past are not likely to

damage the future. But has the progress of medical education in this country been aided at all times by all the physicians themselves?

CHANCES FOR IMPROVEMENT

No man has been longer or more intimately connected with the development and progress of medical education in this country than Professor Welch. It is interesting to note that in organizing the School of Hygiene and Public Health at Johns Hopkins he has associated himself in the first place with another leader, Professor Howell, and has headed several of the chief departments of the school with men not of medical college training but of international reputation in their scientific lines. Public health and hygiene are certainly fields that should be entered by men of the medical profession.

How does a university choose its professors? In the case of a real university, by selecting the most eminent man available in the field, and certainly with little regard for his early college degrees. The remarkable progress in medical education has taken place since the better medical schools have adopted the same method.

Finally, what are the actual reasons why the medical schools do not produce a sufficient number of men for medical laboratory sciences? The first and most important reason is rarely mentioned, and that is, that the laboratories of the medical schools have not even yet been developed up to the university standpoint. The medical school is strictly on a college basis, the instruction is almost entirely by classes, and the departments are considered complete when the staff is sufficiently large to handle the routine curriculum courses. This is the college standard all over the world. Such a college is merely for educating the individual, and not for training and offering the atmosphere and opportunities for the mastery of a science and the investigation of its problems. This is the duty of the university. How do the great universities produce chemists, physicists and biologists? They accomplish this by conducting university departments of sufficient size to cover the chief phases of the subject, and by employing not one professor of chemistry in a department, but from four to six. Many schools of zoology have four, five or more men of distinction as professors in the laboratory, and here a student, already educated in college, can obtain a broad and thorough acquaintance with the problems of biology from men investigating its blind channels by observation and experiment.

In the second place, the usual routine inelasticity of the medical course causes the student to feel that he must not miss anything, and he is hurdled through with little opportunity to observe whither he is going. Now, it so happens that many of the medical colleges of England, and most of them on the continent of Europe, have more elastic arrangements; the student often spends longer in his actual medical education and almost always has an opportunity to ease up on the routine and become interested in some particular subject or branch of the medical organization. Then, particularly on the continent, the first condition comes into play. The laboratory departments of the medical school are developed on as complete a basis as the university departments, and there is not only one, but often four or five men of eminence working in the same laboratory of anatomy. This is often true even in the small universities, such as Freiburg, Würzburg and Jena. Therefore, the elasticity of the curriculum per-

mits the best students to become interested in the fundamental sciences, and the development of the departments in the medical schools is sufficiently mature to allow them not only to care for such men, but also to attract many of the best to come.

In this country there have been only a few such laboratories in the medical schools; but these have worked. The one in particular which recommends itself to my mind was the laboratory of anatomy at Johns Hopkins as conducted by the late Professor Mall. There was more than one professor of eminence in the department, and it had developed on a university basis. This laboratory, through the personality and ability of Mall, was able to perform the miracle of transmutation. It appealed to the medical student who had come with the primary object of entering the practice of medicine, and convinced him that medicine cannot live by practice alone, but that new truths await discovery on which the progress of the profession depends. The laboratory flourished to such an extent that it has supplied the heads of the anatomic departments in eight medical schools and has exerted a profound influence on all the rest. The salaries offered to induce these men, usually poor, to come into anatomy were notoriously small; but under Mall's influence there was no hesitation to accept low living for high thinking. Few, if any, other medical laboratories can boast of such a record, and it was established in spite of conditions.

Mall was a medical graduate, but there were no "lay professors" to his eyes. There were only those who possessed a knowledge of their subject and could contribute discoveries in aiding its progress, and others lacking such qualities. The first group he considered valuable; the second was not. Only on such a classification can medical science and medical education be improved.

Another anatomic laboratory of university dimensions is developing in the University of Minnesota Medical School. There are now at least four full professors and several assistant professors, about half with and half without the M.D. degree, engaged in investigation and teaching in this institute. It is interesting to recall that a university trained physiologist is the dean of this college. When we have most of the medical schools of the country with laboratory departments developed to this extent, there will no longer be a scarcity of medical students coming into laboratory work. But on the contrary, not only will enough of them desire a scientific pursuit to man the medical laboratories, but medical men will compete for the chairs of biology and the natural sciences in the universities.

Medicine, as well as every other profession, needs masters in their field, and past history has shown that they can be relied on to extend the field and properly teach the subject. A school need not desire an eminent physician as professor of anatomy, since such a man would rarely be an eminent anatomist; nor need it desire an eminent chemist as professor of medicine since, again, such a man would not be an eminent physician. An engineering school does not select a successful engineer, or even a trained engineer, to teach the fundamental principles of either chemistry or physics to the students of engineering. A medical graduate who desires to teach physiology does not become a physician but must become a physiologist. As Bernard Shaw puts it, "It scarcely becomes a waiter to have a barrister for a son; neither does it become a barrister to have a waiter for a father."

The increasing opportunities for full time clinical teachers and investigators, along with the tendency to include a fifth clinical year in the medical course, are factors which will obviously tend to make it still more difficult to attract the medical graduate into the laboratory subjects.

Lastly, the question of university salaries is a vital one, but let us not be deceived into thinking that this is the only element involved in keeping medical men out of the laboratories. The conditions mentioned above are certainly of great importance. Proper salaries, however, will do much to put the laboratory teacher on a more efficient and dignified basis. There are still two opposing parties in the campaign for the "full time" clinical teachers, but there is a single fusion ticket which every one favors for the "full paid" laboratory teacher. The directing professor of a laboratory department in the leading medical colleges should receive a \$10,000 salary, and other members of the department should be paid accordingly.

There must always be two parties to medical progress, the individual, it matters not who, contributing the fundamental discoveries, and the doctor of medicine, with a keen appreciation of the significance of things, to apply the discoveries in practice. The physician will appreciate the more keenly when he is trained by the best masters in the principles of the sciences which are certain to contribute the discovery.

HOSPITALS OF GREECE

CARL E. BLACK, A.M., M.D.

Major and Deputy Commissioner, American Red Cross Commission to Greece

JACKSONVILLE, ILL.

Reports received in Washington, prior to the sailing of the American Red Cross Commission to Greece, laid emphasis on the needs of the Greek hospitals, which were said to be overcrowded and short of supplies and equipment. Following up this information I made a careful study of the hospital situation as one of the first duties of the commission. The policy of detailed inspection was followed, and information secured at first hand regarding the situation.

The natural independence of the Greek character, and pride in Greek institutions, often masked the real need, and we discovered early that it was necessary to visit each hospital and to learn the actual conditions from personal investigation. The casual visitor was usually told by those in charge that, while there were many things they could use if they had them, they were getting along as well as the situation would permit. The true condition developed only after the establishment of mutual confidence. Some of our professional visitors, meeting well trained Greek physicians in charge of large hospitals, were at first led to believe that they had ample supplies and equipment. In one hospital we found 300 patients without proper beds or bedding, and the supply of drugs and other essentials was absolutely exhausted; and yet the pride of the officer in charge prevented him from feeling at liberty to acknowledge the real situation developed by the war. When later we sent a consignment of a few essentials, he was exceedingly grateful.

Another reason for making a personal investigation of each hospital was the criticism often heard of whole-

sale and indiscriminate distribution of supplies in other countries. The Greek commission decided that it would not be guilty of this error if it was possible to avoid it. Relief was administered only after a careful personal investigation by either the head of the department or some member of his staff, usually a physician, but if not, always an American trained nurse. The head of the department personally visited more than half of the hospitals to which relief was given, and many of them were visited several times.

Some well meaning friends in Washington and Paris thought that Greece had been in the war such a short time that there could be no great need for aid in Greece or in the Greek hospitals. The same argument made against aiding Greek hospitals would have applied equally well to France. These countries were not appealing to the American Red Cross as paupers and suppliants, but as our allies engaged in the greatest struggle of history and with the most desperate and unscrupulous combination of enemies ever met by the soldiers of peace-loving nations. It was just as much our duty to aid brave little Greece as brave big France. Both were prosperous, and in normal times able to meet their civic obligations. France had had many years of peace in which to develop her resources, while Greece had been almost constantly at war since 1912, and in addition had been torn asunder by internal dissensions and revolution, resulting from the disagreements between a pro-German king and a pro-Ally people. This struggle between the Venizelists and the Royalists was as much a part of the whole struggle of the Allies with Germany as was the Battle of the Marne.

The state of transportation and the difficulties arising out of the complicated control called for great patience and farsightedness in dealing with the problems. However, the assurance given to us by the officers of the national Red Cross, and the fact that the Greek government gave us free transportation of supplies from New York up to 300 tons a month, led us to believe that the first consignment of supplies ordered before leaving the United States would be in Athens on our arrival. Soon after we had made a preliminary survey of the situation, we began to send additional requisitions to Washington for the things we found absolutely necessary. The slow way in which supplies were received in Greece was no doubt due to conditions that could not be controlled, but it prevented the amelioration of much suffering and made impossible the saving of many lives.

We were assigned by the Greek government to the department of Mr. Jean Athanasaka, undersecretary of state for war, bureau of hygiene and sanitation, through whom we developed the lines of work which the American Red Cross could undertake for relief in Greece. This broad-minded and public-spirited official used every effort to forward our work.

The sudden cessation of hostilities in the Balkans was looked on by many who were not on the ground as another reason why American Red Cross assistance was no longer needed, in forgetfulness of the fact that it was impossible for the civilian, or even for the Greek government, to secure necessary supplies in the market, regardless of financial ability. Furthermore, while many citizens of Greece were rich, the government was poor. In fact, the Greek army was still intact, doing more or less active service in Russia, Asia Minor, Thrace, and Macedonia a year after the signing of the armistice; and the epidemics of influenza and of typhus kept a heavy burden on the hospitals.

CONDITIONS RESULTING FROM WAR

The war had wrought havoc with the Greek hospitals. Practically all the civilian hospitals had been converted into military hospitals. The epidemic of influenza was quite as widespread and severe in Greece as elsewhere. They had passed through epidemics of typhus in Macedonia, Epirus and the islands; and on looking back at the situation, it is easy to see why practically all of the hospitals had exhausted their reserves of equipment, stores and medicines. The richest and best equipped hospital in Greece had no adhesive plaster, gauze, roentgen tubes or cotton, not to mention many other hospital essentials, and during the six months following our arrival was not able to obtain these on the market. Many hospitals had no hypodermic syringes or needles, and no thermometers or anesthetics, and lacked many other necessary but less important items. As soon as relations of mutual confidence were established, we received almost daily, from both civilian and military hospitals, requests for the most ordinary, everyday supplies which they were unable to obtain from any other source than the American Red Cross.

There had been no adequate accumulation of stores since the Balkan wars for the day of need. The country was plunged into active participation in the world war by a blockade which made it impossible for her to import even the most essential articles. For the sake of the argument we might still admit that her wealthy citizens were financially able to supply all her needs; but however willing they may have been, to do this was impossible. The world's stock of hospital supplies was all in the hands of the Allies or the Germans. Under the circumstances, this meant that all the surplus available to allied or neutral countries was in the United States, where it was impossible for the private purchaser to buy them or to secure transportation for them. England and France had no surplus stocks to sell. The United States was supplying them. All the world's supplies were required for the Allied armies, and were under Allied control. Prior to her entrance into the war on the side of the Allies, Greece was practically shut off from the world's markets and got little or nothing; and after she entered the war she got only such portion as was necessary for keeping her army in the field and supporting her military hospitals, which was indeed a scanty allowance. There was no way in which the civil hospitals could be supplied, and at the time the American Red Cross arrived in Greece, practically all the reserve stores had been exhausted. In fact, it was this very situation which caused the Greek Red Cross, in May, 1918, to send an appeal to the American Red Cross, and which determined the national Red Cross in Washington to send a commission to Greece.

A second object in making inspections of Greek hospitals was a desire to acquaint the American public with modern Greece, the home of the father of medicine, Esculapius, and his great successor in the science of healing, Hippocrates. Greece has made a wonderful start in providing her people with hospital facilities. She is far ahead of any of her neighbors, owing to the keen intelligence and the widespread education of the Greek people; and the conditions of need we found were due to wars and epidemics, and not to a disregard and ignorance of the value of such institutions. We also hope that in view of our acquaintance for several months with this splendid little nation, the Greek people

will be willing to accept a few suggestions by way of constructive criticism. I have left out of this general statement many details, but these will all be found in the reports of the commission to the national Red Cross in Washington. Accompanying these will be about 200 pictures of Greek hospitals and their personnel.

While most of the hospitals were originally intended to provide only for the poor, there is an increasing tendency to extend the service to all classes. Many of those, even in small communities, have excellent buildings, beautifully situated, often surrounded by well kept gardens, and showing a desire to make the surroundings attractive. Often the absence of the same attention to comfort and attractiveness on the interior is in sharp contrast to the surroundings. One is struck by the absence of evidence of active participation of the Greek Orthodox Church in the organization of their hospitals. There seem to be no orders of monks or sisters wholly devoted to the care of the sick. The development of hospitals has been left largely to lay initiative. On the other hand, almost every hospital has its chapel. What Greek administration has already done in building and equipping hospitals is an excellent illustration of the enlightened progress which this people has made. They have always kept in close touch with France, Germany and Italy, and the methods of organization and equipment used are largely drawn from these sources. This makes the situation more difficult for an American to understand. One sees little in Greece to show contact with England or America.

DATA COLLECTED

In making hospital inspections, we devised a brief form, in order to have the reports uniform. It was expected that these data would provide only the essential facts. This form gave the name, location, character, management, and superintendent, directress or matron; physicians, surgeons and specialists in charge; hospital records, training school, nurses employed and how trained, number of beds and whether free, paid, surgical, medical, children, obstetric, soldiers or special; the facilities offered by operating room, dressing room, laboratory, roentgen department and pharmacy; and remarks covering any other interesting and important facts.

Numerous conferences were held with members of the ministry, hospital officials, physicians and others. We always found them actively interested in developing their institutions.

One circumstance that seriously interfered with preparing detailed reports on the Greek hospitals was the rapidly changing conditions as the country passed from war to peace. Many temporary hospitals had been established. Practically all civilian hospitals had been converted into military ones, and the process of reorganization was rapid and involved constant changes in our data. For example, one hospital of about forty beds was twice taken over by the military and twice returned to its civilian management; was through two epidemics of typhus and one epidemic of influenza, and at the time of our second visit was again administered by the military authorities to provide hospital care for a second epidemic of influenza among the soldiers. While this is rather an extreme case, it illustrates one of the difficulties we encountered in estimating the value of a given hospital. It is hardly necessary to say that a civilian hospital that has passed through so many

changes of management within two or three years has little left with which to begin a normal civilian hospital life in a country so far away from the source of supply as Greece has been during and since the war.

HOSPITALS OF EASTERN MACEDONIA

This report would be incomplete without special mention of the hospitals in eastern Macedonia, which was the main scene of relief work by the American Red Cross. This district of Greece must be classed with Belgium and Serbia in the suffering that the war brought on its citizens. They not only suffered the natural privations and hardships due to being situated in the war area, but they had recently passed through two wars that had entailed great suffering. Prior to this, they had lived under Turkish rule, which gave them constant hardship from misgovernment; and during the long years in which the grasp of Turkey over her European territory was weakening, Macedonia was the scene of a fierce Bulgarian propaganda almost as devastating as war. The hatred of generations of conflict was around them. Thousands (150,000) were carried from their homes into Bulgaria, where they existed two years under a system of cruelty worse than slavery. Their cities and villages were burned and pillaged, and after the Bulgarians were driven out desolation reigned everywhere. This was the condition when we first entered eastern Macedonia at Kavala early in November, 1918. The deported population was just beginning to return. The military hospital of Kavala was a tobacco warehouse where tobacco crates took the place of beds. The sick were pouring in, but there was little or nothing we could do at that time to help them. The civil hospital had five typhus patients and no others. There was no other provision for the sick in a city which had claimed more than 40,000 inhabitants. Drama was a little better off, but not much. Her small civilian hospital had been taken over for military purposes, and when abandoned by the army was little more than a shell, without supplies or equipment, although this city of 25,000 inhabitants had not suffered to the same extent as some of her neighbors. Seres, formerly a city of 20,000, had suffered more than either Kavala or Drama, and her hospital was practically ruined, so far as service to the sick was concerned, until it was refurnished and its supplies replenished by the American Red Cross. The villages had suffered equally. The sick were on every hand, and there were no supplies or equipment for the most essential comfort.

In aiding these institutions, we encountered many serious difficulties. The long distance from Greece to America, and the great demands of other countries on American supplies, were great handicaps. The time consumed in getting supplies seemed intolerably long, and not infrequently when they arrived the quantities were altogether insufficient and many important things were missing. Much time was lost by the sudden decision to reorganize the work of the Red Cross in the Balkans and place the several commissions under a general commission for the Balkan states. Not only was time lost by this reorganization, but many supplies intended for Greece were diverted to other fields. No doubt, in some cases the conditions in other countries were more urgent; but more often the diversion of supplies was due to a misconception of the situation based on information from sources that could not have had sufficient and proper information.

CLASSIFICATION OF GREEK HOSPITALS

While the hospitals of Greece could naturally be divided into three classes, civilian, military and special, during the active progress of the war they were all military. During this stage the military hospitals were divided into permanent, temporary and civilian, taken over for military purposes. It was necessary for the government to establish purely temporary hospitals in addition to those taken over, and some of these could scarcely be called hospitals. For example, one so-called hospital was nothing more than a series of single walled tents in which more than 800 patients were lying on the ground with nothing but thin mattresses or blankets under them. These conditions were the best that could be had at the time. A number of hospitals, such as hospitals for the insane, were visited, but no attempt was made to study them in detail, as the extending of emergency relief was all that the American Red Cross could undertake.

We inspected and have reports on practically all hospitals in Greece, of which forty-seven were military (or being used for military purposes at the time) and fifty were civil, making a total of ninety-seven. Seventeen of those classified as military will return to civilian service as soon as the country is on a peace basis. These hospitals have beds for more than 20,000 patients. Practically all the military hospitals and the majority of the civilian were given substantial assistance by the Greek commission of the American Red Cross.

A word is due regarding the way in which our work has been received in Greece. As has been said elsewhere, we first met an attitude of pride in their institutions and a spirit of independence and reserve in seeking aid from the American Red Cross. We have rarely been made to feel that there was any disposition to impose on us in any way. On request they have stated their needs fairly and have accepted what we could give them in an attitude of delighted appreciation. The files of the Greek commission of the American Red Cross will show a large number of letters of appreciation from managers, physicians and boards of directors, of the most kindly and appreciative tone. Often the name of the "American Red Cross" will be found on the marble tablet containing the names of benefactors which is usually placed in the main hall of a Greek hospital.

CONCLUSION

The time for reorganization is at hand. Greece, which is a peace-loving country like America, is looking forward to a long period of peace when there will be opportunity to develop and improve her institutions, and we have had ample indication that she will then turn to her allies for suggestions and help. The previous leadership led her to provide only for the army and for the poor, with the result that in most of the hospitals the elements of comfort, cheer and social and moral improvement, which we consider so essential, are lacking. The vase of flowers, the screened window and porch, the dainty tray, the music, and many other things which come with the training, skill and human touch of the trained nurse will change these bare wards from couches of distress and suffering to homes where the sick may be surrounded by all the comforts of a home with the addition of all those touches of human sympathy which an educated and trained nurse instills. The three outstanding needs of most Greek hospitals are, modern sanitary appliances, fly screens, and proper

training schools for nurses. To meet this last need the American Red Cross will establish in Athens a training school for nurses on modern American lines. The splendid educational advancement of Greece along other lines makes her ready and, judging by many expressions made by her citizens, willing to accept new standards for her hospitals. It is in this that American influence can be of great service. Our constant visits to the hospitals and consultations with the managers, physicians, nurses and others interested have convinced us that there will be radical changes in the hospital ideas in the near future. In another chapter of this report will be found a brief detailed analysis of each hospital. In securing these data we have seen every department of almost every hospital in Greece, and we trust that the accumulation of data and the analysis of our findings may lead to a new understanding of what the hospital stands for in a community. During our inspections we uniformly made a list of the more essential needs of each institution, and in making our requisitions on Washington, Paris and the Balkan Commission for supplies, we based them on the actual conditions. Our great difficulty was to get the supplies most needed.

EMPYEMA AT THE CINCINNATI GENERAL HOSPITAL DURING THE INFLUENZA EPIDEMIC*

JOSEPH RANSOHOFF, MD., F.R.C.S. (ENG.)
CINCINNATI

As a natural result of the pandemic of influenza of 1918-1919, there has accumulated a literature sufficiently extensive to form a library of moderate size. A large proportion of published papers deal with the subject of empyema; and since for the first time in the history of the disease, hundreds of thousands of men, in the prime of life, were congregated in the close quarters of army camps and camp hospitals, it is natural that the preponderance of articles should treat of the disease and its sequelae as observed under these conditions. This fact lends justification to a presentation of this study of empyema, based on experiences during the epidemic, in the surgical services of the Cincinnati General Hospital.

An apology might seem indicated for the incompleteness of many of the records, particularly the bacteriologic; but this is accounted for by the fact that there was a dearth of physicians in civil life and that at one time seventy of the nurses were ill with the disease.

From Oct. 1, 1918, to May 1, 1919, there were admitted to the Cincinnati General Hospital 3,688 cases of influenza, of which 625, or 16.6 per cent., proved fatal. Whereas this death rate from influenza appears high, it must be remembered that only the seriously ill sought admission to the hospital wards. Among these 625 deaths, five were in cases of empyema which came under our surgical care. Altogether, fifty cases of empyema were transferred from the medical to the surgical service, or were primarily admitted to the surgical service, though the latter was not often the case. In many of the 625 cases, empyema was recognized by exploratory aspiration, but was a small factor in the death rate. As was experienced elsewhere, a very large proportion of the patients died from the toxemia inci-

dent to the pulmonary complication, before the condition of the patient or the course of the empyema warranted surgical intervention.

In many of these quickly fatal cases, pleural effusion of greater or less extent was doubtless present. It was early recognized by the medical staff that influenza toxemia with moderate pleural effusion should be treated by aspiration alone, and that early surgical interference of greater magnitude was apt to be followed by speedy death, whether as a result of the interference or despite it cannot be determined. In our surgical services, aspiration in the cyanotic stage was practiced in only two cases, but both proved fatal. It was evident that the cyanosis was not the result of pulmonary compression from pleural effusion, but was caused by the toxemia due to hemolysis. In two cases, aspiration of small quantities of turbid fluid was followed by recovery.

That later interference in cases of empyema offers a better possibility of recovery is manifest by our series of forty-six cases in which operation was performed, by incision, with three deaths in the hospital and one two days after release. The average stay in the hospital before operation was $14\frac{7}{10}$ days. Some of the patients were not admitted until a day or two after the inception of the disease, and it is therefore fair to assume as an average that at least sixteen days elapsed before operation.

The average age of the patients was 21.6 years, somewhat below the average in military camps; fourteen of the patients were under draft age. It might be inferred, therefore, that the low mortality rate in our series of empyema cases might be attributable to the lower average age of our patients, in accordance with the well known fact that metapneumonic empyema is much more tractable to surgical interference in young subjects than in those of more advanced years. Curiously enough, however, there were three deaths among the fourteen patients under draft age, their ages being 15, 16 and 5 years, respectively. On the whole, the age incidence of the disease in the civil practice of our hospital did not differ materially from that which obtained in the military and camp hospitals.

It may well be claimed that the type of empyema which prevailed in the influenza epidemic among the civil population differed in severity from that observed in military hospitals. It is regrettable that our bacteriologic examinations were not complete; the streptococcus alone was found in eight cases; the pneumococcus in seven; both streptococcus and staphylococcus in nine; and both streptococcus and pneumococcus were found in six cases.

The treatment instituted in all cases of empyema was that of drainage with immediate occlusion of the pleural cavity, after the manner I have previously described.¹ Because of it, or despite it, the mortality rate was only 9 per cent.; although certainly in two, and possibly in three of our cases, there was a double empyema, necessitating bilateral drainage. In none of these three cases, however, did the disease affect the two sides at the same time; there was an interval of from two to three weeks between the operations.

The mortality rate after empyema operations is ordinarily not considered very high, and yet we find that "in 299 consecutive cases observed in so excellent an institution as the Mount Sinai Hospital, during the period of ten years, the mortality reached the formidable

* Read before the Southern Surgical Association, New Orleans, Dec. 16, 1919.

1. Ransohoff, Joseph: A Simple Method of Draining Empyema, J. A. M. A. 66:1196 (April 15) 1916

figure of 28 per cent."² The low mortality rate in our series (9 per cent. in forty-six cases, including some bilateral) warrants the publication of this report, and justifies in a measure the assumption, or perhaps presumption, that the method of treatment bore some relation to the favorable results.

The operations were for the most part performed under local anesthesia (in twenty-nine of forty-six cases), and whenever the intercostal space was ample, rib resection was not resorted to. In twenty-six cases rib resection was performed, and in twenty, intercostal drainage without rib resection. An ordinary drainage tube was used, with collapsible tube attached with or without a shield. There is always some danger of the shield's coming away from the rubber tube. One of our patients, a lad of 16, still carries such a shield within the thoracic cavity. He left the hospital forty-one days after operation, without the slightest discharge; the roentgen ray shows the shield in close relation to the chest wall. In most cases a tube was used without a shield, being introduced through an opening just large enough to permit its introduction. The incision was made at the most dependent point in order to assure efficient drainage; but not so near the posterior median line as to interfere with the free passage of the pus into a receptacle. The pus was, of course, never allowed to escape rapidly, and I am quite sure that the fluttering of the mediastinum, which is such an element of danger in rapid evacuation of the pleural contents, was thus avoided. The pleural opening and the outer incision were at once made watertight by sutures.

In only one instance did death occur on the table, and this in one of the extremely toxic cases referred to above. Irrigation with the chlorinated soda or other solution was not practiced in our cases during the early postoperative stage, although from military hospitals came paeans in praise of this procedure. In the later stages if the discharge continued, we resorted to the use of the Carrel-Dakin method with good results. As a primary measure, while the patients are still very weak, I believe that there is not a little danger connected therewith. It should always be borne in mind that in a considerable number of cases of empyema, particularly those following the insidious creeping pneumonias of influenza, subpleural abscesses, often of diminutive proportions, are discovered; it is because of the rupture of one of these abscesses that the pleurisy in reality develops. Injection of an irritating solution into the pleural sac is, therefore, always associated with the danger of irrigating the bronchial tree, the only tree for which irrigation is contraindicated. In not a few instances in which irrigation was practiced later, the fluid was expectorated by the patient and further irrigation had to be avoided. In only one of our cases did we have the unusual complication of septic peritonitis:

Briefly, the case was that of a medical student in a training camp, who, because of dislike of the surroundings in the military hospital immediately after the armistice, was discharged as well, although he had been ill for ten days. He entered the hospital with an empyema, streptococcal in character, and was operated on forty-four days after the inception of the disease. Three weeks later there developed what seemed to be a perforative appendicitis, for which a laparotomy was done. Streptococcal peritonitis was found; the appendical peritoneum was injected, though not more than the rest of the peritoneum, with plastic lymph and seropurulent effusion. An open pulmonary fistula necessitated the

discontinuance of the Carrel-Dakin treatment. The patient recovered and left the hospital with a small cavity 266 days after his admission. He has since been sent by the government to Roswell, N. M., for tuberculosis.

The average duration of stay in the hospital after institution of drainage was forty-three days; at the end of this period twenty-nine patients left with the wounds entirely or practically closed and the rest with considerable drainage. This seemingly high average is due to three patients, remaining 96, 203, and 266 days, respectively.

In order to check the end-results in our cases, the patients were followed through the social service. One man died shortly after leaving the hospital; his condition at the time was very serious and he was released against the advice of the physicians. Eight who recovered could not be traced by the social service. Of the rest, one is being attended at the surgical clinic for a slight pleural fistula, three have reentered the hospital for secondary operations, while the remaining patients have been found by the social service to be in good health and at work.

We may, therefore, state that our results with occlusion drainage have been satisfactory. The hospital mortality rate was 9 per cent., including fatal issue in one patient removed against advice. I am not aware that equally satisfactory results have been published from any of the large military hospitals. In comparing results, it would be unfair to charge our good results to the method of treatment alone, since in the large airy quarters of our new permanent hospital better results are obtainable for the relief of respiratory affections than in the cramped quarters of hastily constructed military camps. This factor, however, is not alone responsible for our favorable statistics, since it is evident that the mortality rate of 16.6 per cent. for influenza per se in the Cincinnati General Hospital is only a little less than the average in military camps. It is almost needless to say that in the after-treatment of our drainage cases the patient was quickly advised and instructed in the use of forced expirations by means of Woulfe bottles, and in such thoracic gymnastics as would aid in the expansion of the lung.

CONCLUSIONS

Finally, if I were permitted to interpret the experiences which we have had at the Cincinnati General Hospital with empyema during the period of the influenza epidemic, and with its treatment, I would crystallize them in the following conclusions:

1. Empyema complicating influenza is in itself not responsible for death; too early operative measures should be avoided and should be limited to simple aspiration.

2. Operation not earlier than the end of the second week gives the best results. Rib resection is indicated only when sufficient space is not at command without it.

3. General anesthesia is not necessary in most cases, but in our experience does not increase the mortality rate of the operation.

4. The old methods of drainage should be given up for some type of the occlusion method, by which the entrance of air into the pleural cavity is prevented and the egress of pus facilitated. A suction apparatus attached to the tube is deemed unnecessary.

5. Flushing of the cavity with Dakin or other solution is unnecessary, except when defervescence does not occur, which indicates that spontaneous sterilization of the cavity is not progressing normally.

6. The small pneumothorax which sometimes remains after the healing of a cavity, as has been demonstrated by the roentgen ray, is negligible, since it disappears spontaneously in a short time.

Twenty of the operations were performed by myself, the remainder by various attending surgeons of the hospital, to whom I am greatly indebted for carrying out the suggestions which I believed essential to securing so low a mortality in the treatment of our empyema cases.

The fact that we were enabled to trace end-results in all but eight of our cases shows one of the many advantages of an efficient hospital social service.

THE TREATMENT OF MUCOUS COLITIS *

W. A. BASTEDO, M.D.

Assistant Professor of Clinical Medicine, Columbia University
College of Physicians and Surgeons

NEW YORK

The name mucous colitis (myxomembranous colitis) stands for a poorly understood clinical entity, and I shall therefore preface my remarks by a brief review of what is implied in the condition as I understand it. It may be defined as a condition characterized by the formation in the large bowel of great quantities of abnormal mucus. It should not be termed "colica mucosa" or "mucous colic," for colic occurs in only a small proportion of the cases. The disease may occur at any period of life from infancy to old age, and contrary to the prevailing belief, is encountered in males quite commonly as well as in females. It is probably hereditary to some degree, as I have found it repeatedly in parent and child, when I have usually noted in the roentgenogram the presence in each of the same type of redundant or looped colon, often with ptosis.

Though mucous colitis is of frequent occurrence, yet it appears to be infrequently recognized. The importance of its recognition is evident if we realize that, although at times the condition of the bowel may be merely incidental to more important lesions, it is often most prominently associated with serious states of physical debility or of mental instability. I would not say that it is a cause of these, but it does strikingly increase their manifestations, and its cure is not infrequently accompanied by their disappearance.

In severe mucous colitis the three outstanding manifestations are: abdominal pain, intestinal putrefactive toxemia and neurotic manifestations. Whether the patients are classed as suffering from colitis, or from neurasthenia or psychoneurosis, or from autointoxication, the mucous colitis must be treated or the patient will not be relieved of the other manifestations.

Usually, the patients seek a physician, not because of the colitis, but rather for persistent constipation, abdominal pain or distress, lack of physical energy, obstinate or recurrent headache, failure of physical or intellectual vigor, mental depression or complete nervous breakdown. Though they may have noticed strings of mucus in the stools, the patients commonly do not mention this unless interrogated. Hence, in a patient showing nervousness, depression of spirit, and lack of the usual forcefulness, it is well to search for a possible mucous colitis.

DIAGNOSIS

As there is no distinguishing factor other than the mucus, the diagnosis rests on: (1) the observation by the patient of the passage of mucus, either as strings accompanying the feces or as a complete mucous stool; (2) the finding of the characteristic mucus in a stool submitted; (3) the detection of the characteristic mucus after a test dose of castor oil or a test colon irrigation, or (4) the observation through a sigmoidoscope of a dry mucous membrane in the upper rectum to which are clinging the heavy, tenacious sheets of mucus. If mucous colitis is sought for only when there is colic, many of the most important cases will be overlooked.

Mucus.—This is tenacious and appears mostly in yellow, brown or sometimes black jelly-like masses, or in more or less desiccated plaques, strings, ropes, or scablike membranes. The strings may be many inches in length, and on being teased out in water prove to be casts of the bowel, or broad ribbons. Patients sometimes mistake them for intestinal worms. The mucus adheres with great tenacity to the wall of the bowel, so that when encountered postmortem it is removed with difficulty, even with forceps; von Noorden reports that he was unable to drive it off with a strong stream of water from a hydrant. Hence, it is not uncommon to find blood spots on the expelled mucus, as if it had been torn away like a scab. As a rule, the mucus bears only a few leukocytes and is without fibrin. In some of the persistent cases I have frequently noted about the mucus an odor that is entirely different from that of the stools, slightly suggestive of dead fish just thrown up on the beach and before they have become offensively putrefactive.

Besides mucus there are occasionally found quantities of blackish or brownish, gritty, irritating intestinal sand. Some authors report the frequent presence of blood in the stools (Mummery found it in 60 per cent. of cases), but after thousands of examinations I can report that this is not usual, and occurs mostly when the scablike membranes come away. It is regularly present in cancer cases, and frequently with polyposis; but in these cases the mucous colitis is not the important feature.

Pathology.—The changes are indefinite; the colon sometimes shows very slight alterations or even rarely no recognizable lesion, but usually the mucous membrane is more or less damaged. In some of the colons removed at operation the mucous membrane of the cecum and ascending colon has revealed a universally distributed area of inflammation, and the whole wall of this part of the intestine has shown atony, dilatation and poor nutrition. In some cases Keith has demonstrated absence of the normal nerve elements of Auerbach's plexus with consequent cecal and colonic stasis. The colon is often redundant or looped, and there is sometimes laxity of the abdominopelvic walls with ptosis of the transverse colon and of one or both flexures, with perhaps a movable cecum. In the persistently toxic cases, pyorrhea alveolaris and gastric achylia are not uncommon findings. Rarely cancer of the colon, polyposis, diverticulosis or some other localized lesion may underlie the condition. Not infrequently the descending colon is found in a spastic state.

Pain.—In a large proportion of the cases a certain amount of discomfort is manifested at some stage of the disease. It may range in intensity from nothing more than a little soreness to paroxysms of the most distressing colic; its location may be variable or con-

* Read before the Alumni Association of the University of Buffalo Department of Medicine, June 21, 1919, and the Medical Society of Atlantic County, N. J., Nov. 14, 1919.

stant, and in the latter event it has not infrequently led to a futile operation for some supposedly serious abdominal or pelvic lesion. At times, the whole colon, or a part of it, is found to be tender. The colic is the direct result of the attempt by the bowel to expel long-retained and clinging mucus; persistence of the attacks may be taken as an indication that not all the mucus has been liberated. The mucus, acting as an irritant, induces spasmodic contraction of a portion of the colon, and the pain is due to tension in the distended portion above this. The spasms do not produce the painful manifestations, for, as Hurst has shown, bowel pain comes from distention, not from contraction. The pain ceases after the reestablishment of the peristaltic reflex with dilatation below and contraction above.

It is to be remembered that pain of significant degree is lacking in some of the cases, and in many is absent for considerable periods. Yet even during the painless periods the symptoms are more manifest when the mucus is retained, and become less so following its expulsion.

Constipation.—In some cases several stools a day are passed, yet constipation exists, for the cecal cess-pool seems never to be emptied. Constipation is not necessarily a condition of infrequent defecation, but is rather one of insufficient or retarded defecation (Hurst); colon irrigations have shown that there may be considerable cecal retention of putrefactive contents, though the bowels seem freely open.

Intestinal Putrefactive Toxemia.—Without doubt, the neurotic manifestations and the condition of mental and physical fatigability may in many instances be traced directly to a chronic toxemia caused by the absorption of harmful chemical substances formed in the bowel. And it is probable not only that the constipated bowel of mucous colitis favors bacterial proteolysis, but also that the damaged mucous membrane promotes the absorption of deleterious material. The subject of intestinal toxemia is too large to be dealt with here; it is important to remember, however, that quite often the treatment of mucous colitis involves extensive consideration of the associated toxemia. There may be mucous colitis without putrefaction of the colon contents, or there may be putrefaction of the contents without colitis, but the two conditions are often associated.

COMPLICATIONS

Occasionally we encounter bronchial asthma, urticaria, angioneurotic edema, or erythema, complications which suggest either protein sensitization as a result of absorption of minute amounts of unchanged protein through the diseased bowel wall, or the possible absorption of some chemical formed in the bowel. For instance, histamin is at times a product of intestinal putrefaction, and when absorbed in sufficient amounts is capable of producing asthma, urticaria and angioneurotic edema.

A phenomenon, usually associated with gastric atony and observed by me in a few cases, is tetany.

Nervous or Psychic Manifestations.—Many of these patients, though not by any means all, have a variety of nervous symptoms. These may range all the way from a simple impressionability and hypersensitiveness in insignificant matters to severe nervous breakdown or such mental instability, lack of self-control and irresponsibility of action as to bring the patient to the borderline of insanity. Indeed, it is often quite impossible to decide whether the mucous colitis or the

psychoneurosis is the primary condition. Conspicuous in many are lack of self-confidence, absence of initiative, autosuggestibility, spells of discouragement, and fatigability, both mental and physical. Interesting are the phobias, such as the dread of visitors, of riding in a train, and of being alone at home or in the city streets. The colitis may begin with, or be aggravated by, a nervous strain, such as worry over money matters, over a wayward child, over a husband who drinks or over some skeleton in the closet, or by the assumption of social or business responsibilities that seem utterly beyond the patient's powers.

In a person of dominant type this onset of inability to cope with the daily responsibilities makes for discouragement, mental depression and fits of dejection. I have known strong men, physicians, lawyers, heads of great business, to be overcome by their feelings of helplessness and to burst into tears in my office. I have seen the president of a great concern weep while saying, "Doctor, I cannot face my directors at tomorrow's meeting." I have heard a medical school professor cry, "It's of no use my lecturing any more, I cannot hold the boys, I have lost my power." One patient, a strong man who had repeatedly put up a 100 pound dumb-bell as many as nine times, in the most doleful manner deplored the fact that he could not then get it up once. And each of these men, as the mucous colitis yielded to treatment, regained his old dominance and power. Sometimes such patients have slipped back again, and have been found to have a new access of the colitis.

What is the relation of the bowel trouble to the nervous system? Perhaps in some of the cases there is the same underlying cause for both the intestinal and the nervous symptoms. Among neurologists it is customary, however, to consider that neurasthenia or a psychoneurosis requires two conditions for its production, namely, an underlying mental deficiency, and a provocative factor the most pronounced of which is fatigue. Yet perhaps the underlying mental deficiency is not such an absolute requirement, for Féré says that "fatigue often provokes ideas of negation, persecution and disparagement," whereas Dubois remarks that "exaggerated fatigue may induce neurasthenic states in the best balanced individual." If, then, fatigue is the great provocative factor, may it not be that mucous colitis is one of the important producers of fatigue, either of itself or through the production of toxic substances? Certainly fatigue and fatigability are among the most striking accompaniments of mucous colitis, the patients being readily brought to a state of exhaustion by serious reading, by visitors, by responsibilities of any kind, or by physical exertion. In fact, they may feel fatigued even though they do nothing. So it is my belief that one of the important causes of these neurasthenic or psychoneurotic conditions is the fatigue or the fatigability which accompanies a mucous colitis.

Furthermore, as mucous colitis may induce fatigue or fatigability, so fatigue from other causes may increase the colitis. Therefore, one of my rules for such patients is "Never get tired, physically, mentally or emotionally."

PROGNOSIS

I have seen many patients in serious nervous states, who, after the cure of the bowel trouble, have ceased to be more than normally nervous; and because of the possibility or probability of such a happy result, I lay stress on the treatment of the bowel. I believe that

in a large number of these cases a cure is possible, but usually only after persistent treatment for a long time. And I believe that continued or repeated severity in the symptoms is often the result of neglect by the patient or the physician. The classification of the patient as a "neurasthenic" makes the outlook hopeless, for the physician then does nothing. The height of absurdity was reached by a speaker at a recent meeting of the Pennsylvania State Medical Association, when he said that "the prognosis is absolutely hopeless, the treatment is nil, and the sole prophylaxis would have been to sterilize the grandfather."

TREATMENT

In determining the method of treatment, two facts stand out prominently: (1) that retained mucus is harmful mucus, and (2) that the cure requires a long course of treatment. I am wont to tell my patients that a year is the minimum time in which a cure can be effected. The treatment is directed at the prevention of the accumulation of mucus, and at the removal of the associated conditions, such as colic, constipation, intestinal toxemia, disturbed gastric conditions, bad mental states and depressed general health. We shall take up, first, the treatment of the condition when there is no colic, or after the attacks of colic, and then the treatment of attacks of colic.

I. Treatment in Cases Without Colic or After the Attacks of Colic.—This is designed (a) to prevent accumulation of mucus; (b) to overcome constipation and intestinal toxemia, and (c) to improve the nervous and general health.

(a) To overcome accumulation of mucus, one of the best measures is a weekly purge with castor oil, or perhaps calomel and salts, or a purgative blue mass or calomel pill. This may be supplemented by colon irrigations every day or two for a week, and then every three or four days for two to several weeks longer, or once a week for longer periods of time. For this colonic lavage the patient should be on the left side for the first gallon of water in order to clean out the lower colon, and then on the back for the rest of the irrigation in order to enable the fluid to reach the cecum. Sometime preceding the lavage the bowels should be emptied, if necessary by an enema, in order to avoid carrying feces back to the cecum and to avoid starting up by the lavage the defecation reflexes which will prevent the passage of the water into the upper colon. The liquid used should be rather hot, and I regularly employ tap water, though occasionally sodium bicarbonate solution, a dram to the pint (sodium bicarbonate is changed to carbonate by heat). Physiologic sodium chlorid solution is not employed, because it makes the patient thirsty. The amount required is usually from 12 to 24 quarts, and it should be given slowly, with the reservoir about two feet above the patient. Frequently the putrefactive cecal contents are reached only after 4 or 5 gallons have been employed. If the irrigation does not bring out the mucus, this may be expelled one or several hours later. I always consider an irrigation a failure if no water is retained to be evacuated after the irrigation is finished, or if the water returns clear throughout; obviously, in such cases the liquid has failed to get past the spastic descending colon or sigmoid. Recently transduodenal lavage with 4 per cent. sodium sulphate solution has been employed with reported success. I have not used it for this purpose.

It is to be noted that when the mucus is readily discharged from the bowel the patient is safe; danger threatens when the mucus stays in and is not readily loosened and expelled. Many of the patients learn this fact, and when the mucus suddenly ceases to appear they will use every endeavor to clear out the bowel in order to avoid a renewal of their symptoms. Sometimes a cathartic taken the same night as an irrigation that seems unsuccessful may bring away great quantities of mucus that has apparently been softened by the irrigation water.

(b) The treatment of the constipation and intestinal toxemia is that of any form of constipation. There should be insistence on regularity of bowel movements, but restriction of the use of enemas and colon irrigations. I have seen patients who had come to think that any abnormal sensation could be removed only by enema or irrigation, and who had acquired the habit of using these several times a day. The diet must be ample, for in case of lack of food residue it will be necessary to keep increasing the laxatives. A diet containing bran, fruits and coarse vegetables may be effective, but in the beginning this is usually more harmful to the bowel than a mild tonic laxative. Exercise does not help to overcome constipation, except as it may result in increased appetite. There have been many athletes among my constipated patients. If there is ptosis of the abdominal viscera with laxity of the abdominopelvic walls (and these are exceedingly common), the patient should wear an inelastic binder for mechanical support, and should be put on exercise to help to strengthen the abdominal muscles. The patient should drink freely of water.

The best of laxatives is usually a softening and bulk-producing agent, such as liquid petrolatum, cascara agar, phenolphthalein agar, or small doses of milk of magnesia or salts. But these are not always effective and frequently must be supplemented by one of the tonic laxatives, cascara, rhubarb, aloes, senna, or senna with sulphur in the form of compound licorice powder. A measure of occasional value is the retention in the rectum over night of from 4 to 16 ounces of olive or cottonseed oil. In these chronic cases the drastic cathartics may be successful in getting out mucus, but should be employed only seldom. If such measures as these do not overcome the stasis and the toxemia, the question of surgery should be seriously considered.

Hemorrhoids are a bad complication, as they prevent the use of irrigations, enemas or such strong cathartics as castor oil. They may be treated by the nightly instillation into the rectum, by means of a soft rubber ear syringe, of 60 c.c. of warm olive or cottonseed oil to be retained over night.

(c) Improvement in the nervous and general health.

The diet may have to be modified according to the conditions of the stomach and upper bowel (achylia, hyperchlorhydria, gastric atony, etc.), and to overlook these is to fail in the treatment; but, in general, at the outset the diet should be of the bland lactofarinaceous type. Later there may be a gradual transition to a coarser type with sufficient vegetable and fruit. But there should be at all times limitation in the amount of readily putrefactive proteins, as found in animal flesh, eggs, beans, peas and lentils, these being replaced, if possible, by much milk in the dietary. Of these proteins, in my experience, those of chicken and egg are most prone to produce putrefaction; and peas and beans are more harmful when dried than when

green. The coarse diet at the outset, as advocated by von Noorden, is likely to give rise to gastric disturbances, particularly flatulence, and it seems quite rational to assume that an excessive quantity of coarse, indigestible, fermenting food will do more harm to some of these damaged colons than any mild laxative drug. But in all cases the diet should be ample and its quantity insisted on, for these patients readily acquire the habit of undereating because of a suspicion that this, that, or the other article of food does not agree with them.

If there is any definite surgical condition in the abdomen, such as appendicitis, cholelithiasis, adhesions, bands or pelvic disturbances, it should be overcome. In persistent cases, some surgeons operate on the bowel itself: (1) For cleansing and medicating the colon; as by appendicostomy or cecostomy, for the purpose of permitting daily irrigations through the whole colon. But these must be continued for from six months to two years (Mummery), and the procedure is not, in my opinion, a valuable one. (2) For overcoming stasis or for the removal of diseased portions of the bowel, by plication of the cecum, ileosigmoidostomy, cecosigmoidostomy, partial colectomy and complete colectomy. The indications for radical surgery and the choice of surgical procedure I shall not attempt to discuss here.

Occupation, recreation and rest in proper proportion should be advised. The patients must not be allowed to coddle themselves. They should get up before breakfast and not lie in bed in the morning; they should recline when possible, at a later period in the day, perhaps best for one or two hours after the midday meal, and they should retire early. They should give less time than usual to social or business responsibilities or give these up entirely, and they should not receive too many visitors. They should avoid adding unnecessary responsibilities to the necessary ones; for example, in a schoolteacher, the taking of extra college courses on Saturday, and on Sunday the teaching of Sunday School; in a business man the devotion of his evenings to club committees or to study. They should not undertake reading of too serious a character. It is of paramount importance that, for the time being, patients give up their ambitions, whether social or otherwise. They must, however, have some recreation, preferably golf, horseback riding, bathing or other outdoor exercise, or attendance at games in the open air.

The great rule is that patients must never get unduly fatigued either physically, mentally or emotionally. I explain to them at the outset that they are temporarily handicapped, and therefore cannot do as much as normal people. On the other hand, I do not allow them to shirk all responsibility, but try to get them to do as much as lies well within their powers, encouraging them to attempt more and more till their full powers are restored. Some women with money take matters too easily and are prone to become chronic invalids, self-centered, hypochondriac, "hipped" on themselves, and leading useless lives. They go from one physician to another, or to sanatoriums, read numerous books about their disease and its treatment, and refuse to permit their ailment to be forgotten for a moment. These patients should be induced to avoid medical books and constant examination of their stools, and in every way they should be encouraged to use their faculties and their muscles in a sensible manner, neither too much nor too little. A wise nurse is a

great help in managing the daily life of the female indolent patient.

General hygienic measures, such as cold spinal douches, or alternating cold and hot douches, cold morning baths, cold rubbings up and down the spine, calisthenics, and general massage, with very gentle abdominal massage, are of distinct advantage. A help in the treatment is a change of scene to get away from oversolicitous or nagging friends, or from the wear and tear of home or business. He was a physician of deep perception who replied to the inquiries of the overanxious wife: "Madam, your husband needs a rest. One of you must take a vacation." A visit to one of the spas may furnish rest and recreation away from business and friends and amid pleasant surroundings, with the advantages of hydrotherapy and perhaps the daily ingestion of laxative waters. It is well to remember that nervous people do not sleep or rest well in high, mountainous regions.

The use of tobacco and alcohol, and usually also of coffee, should be prohibited.

Bromids, in doses of from 1 to 2 gm. (15 to 30 grains) once or twice a day are indicated for a short time during the most nervous periods.

In severe cases the patient should be put to bed in charge of a competent nurse. It is bad practice, because of the effect of loneliness, to keep the patient in bed without an attendant.

11. *Treatment of Attacks of Colic.*—This resolves itself into measures (1) to relieve pain and neurotic symptoms, and (2) to promote evacuation of the mucus. These patients feel pain keenly and may writhe in the attacks of colic, and they may even throw themselves out of bed.

1. The pain and neurotic symptoms may be relieved by rest in bed, a large dose of bromid, 2 to 4 gm. ($\frac{1}{2}$ to 1 dram) by mouth, a hypodermic of atropin sulphate, 0.001 gm. ($\frac{1}{65}$ grain), with codein phosphate, 0.03 gm. ($\frac{1}{2}$ grain), and hot applications to the abdomen in the form of a hot water bag, electric pad, poultice or stupe, or a hot bath. On account of habit formation in neurotic subjects, morphin should not ordinarily be employed; but when the recurrence is not frequent and the attack is very severe, morphin may be the best remedy. To relieve the colic the best single drug is atropin; it is of no use for the cure of the colitis.

2. To promote the evacuation of mucus one may use (a) a large dose of castor oil by mouth. This acts by making vigorous peristalsis, which, coming from above the mucus, tends to separate this from above downward and to carry it onward, while at the same time it abolishes the spasmodic obstruction through the peristaltic reflex which produces dilatation below and contraction above. (b) Colon irrigations with tap water or a solution of sodium bicarbonate, a dram to the pint, should be given warm and at low pressure (2 feet). On account of the spasticity of the descending colon it may be impossible to get the liquid up into the colon at first, but persistence and gentleness may result in success. Irritants, such as silver nitrate, should not be employed in the already highly sensitive colon.

Often the combination of castor oil by mouth, codein and atropin hypodermically, and colonic lavage will be followed by relief and sleep. But if the attack is very severe and persistent, and especially if the irrigation is unsuccessful, it is a good plan to put the patient in the knee-chest position and to inject slowly into the

colon from one-half to one pint of warm olive oil or cottonseed oil, to be retained over night or as long as possible, a towel being placed over the anus and a rubber sheet on the bed as protection in case of leakage. This injection is often followed by the passage, a few hours later, of the oil and an abundance of mucus, with disappearance of the colic and no recurrence for a long time, if at all.

METHODS OF ADMINISTERING SALINE AND OTHER SOLUTIONS TO INFANTS AND CHILDREN *

JOHN AIKMAN, M.D.

ROCHESTER, N. Y.

The administration of physiologic sodium chlorid and other solutions to replace fluids lost from the body is a valuable method of carrying certain cases over critical periods. Loss of fluid is more serious in children because of the vomiting that so often accompanies grave illness, and because of the difficulty of giving water by mouth. A relative acidosis may easily result, which in a few hours may greatly increase the gravity of the attack. The reduction of fluid is marked in cases with a history of numerous watery stools, characterized by a rapid loss of weight, hollow eyes, and drawn, pinched expression of the facies. It is my object here to present an outline of the several methods of administering fluids, and to discuss their relative merits.

The method of greatest service is that which will permit the introduction and retention of large amounts of fluid with the greatest ease to the operator and with the least danger and discomfort to the patient.

OUTLINE OF METHODS

1. *Administration of Fluid by Mouth.*—If a child can take and retain sufficient quantities by mouth, it is obvious that no other method is necessary, except for special indications, such as a great loss of blood as the result of hemorrhage.

2. *Rectal Administration.*—The introduction of fluids by rectum, either through enemas, return flow tubes, or by the drip method has been employed for some years with satisfactory results. If the fluid is properly introduced, there is no doubt that considerable absorption takes place. The method is objectionable in children, because of factors not encountered in adults. Unless the child is prostrated, he is apt to be restless, making the retention of the tubes very difficult. It takes considerable time to introduce the necessary amount of fluid, and the child is more or less disturbed thereby, which interferes with his rest. The fluid is apt to be promptly expelled, especially in diarrhea, and there is always some doubt as to the amount which has been absorbed. However, a great variety of fluids may be given by this method, and there is no special danger attached to the procedure.

3. *Hypodermoclysis.*—In children, especially very small children, small amounts of fluid can be quickly given by this method through a Luer syringe and an intravenous needle, or it can be given by gravity. We have often given fluid in several different areas at

the same time. The procedure is very painful and causes restlessness, especially in older children. The amount that can be given is quite limited. While absorption is slow it is sure. It is safest to use physiologic sodium chlorid solution, although I once used a fresh solution of 1 per cent. sodium bicarbonate in two children over 5 years of age who were desperately ill with ileocolitis accompanied by vomiting and very frequent stools. No trouble resulted from repeated injection of fluid, and both children made an uneventful recovery; there is always danger that solutions of sodium bicarbonate will change in character and cause a slough. These cases were seen several years ago; under similar conditions today I would give physiologic sodium chlorid solution by another method that would better answer the indications and cause much less pain.

4. *Intravenous Injection.*—It is not necessary to mention all the fluids that may be given by this method. It is estimated that an amount equal to one sixtieth of the body weight can be introduced through the veins, but much more can be used if the loss of fluid has been extreme. Excretion of the fluid begins at once; if prolonged results are to be obtained, it is often necessary to give repeated infusions. The limited amount that may be given and the difficulty of entering the vein of a small child are the chief objections to this method. With proper technic the method is safe, but it will be acknowledged by any one who has tried it that it is difficult to make an intravenous injection on a small, active infant, especially into the veins at the elbow. In order to overcome this difficulty, other methods have been devised.

(a) *Intracranial Injection:* In an infant with open fontanel this offers the best means of introducing fluid into the blood stream. The method was first studied by Tobler and was introduced in this country only a few years ago by Helmholtz. By this technic, the fluid can be injected through the anterior fontanel directly into the superior longitudinal sinus. As the sinus lies from 2 to 5 millimeters from the skin, it can be easily entered if the fontanel is not closed; at the posterior angle of the fontanel the sinus is wider and deeper. The child is held prone on the table by an assistant, while the needle is introduced in the median line just in front of the posterior angle. If the child is quiet, it is very easy to withdraw blood or to introduce fluid; by means of a Luer syringe, rubber tubing and a three-way cock any amount of fluid can be given without removing the syringe. The needle should be short, and the long point usually found on intravenous needles should be filed away. If a glass syringe is attached before introduction of the needle, constant suction may be maintained for the purpose of discerning when the sinus is entered. If negative pressure is not produced, blood will not flow so quickly, while the operator may push the needle through the inferior wall of the sinus, blood flowing only when the needle is withdrawn. This accident may also be avoided if the needle be introduced at an angle, directed backward.

Any solution adapted to intravenous administration can be given in this way; with physiologic sodium chlorid, glucose and other mild solutions there is practically no danger. It is also an excellent method for transfusion of citrated whole blood in infants.

In cases with a closed fontanel, the external jugular vein can often be used successfully.

(b) *Injection in the Femoral Vein:* This method is practiced in this city by several physicians working

* Read before the Rochester Pathological Society, Nov. 19, 1919.

in the venereal clinics and has produced satisfactory results, especially in children. Arsphenamin may be given in this way to very small infants, and although repeated injections have been made on the same child, no serious complications and no cases of thrombosis have been reported.

While it is possible that the method was previously in use by others, it was introduced in this city some years ago by Dr. E. T. Wentworth, who elaborated the following technic, which has since been followed by himself and others:

If the injection is to be made into the right femoral vein, the operator should stand to the right side of the patient, and with the fingers of the left hand palpate the femoral artery as it passes under Poupart's ligament midway between the anterior superior spine of the ilium and the symphysis pubis. The fingers cover the artery while a medium-sized intravenous needle is introduced into the vein just to the left of the finger tips. The needle may be pushed straight in or at an angle directed upward and backward. A syringe is attached to the needle, and constant suction is maintained until a flow of blood shows that the vein has been entered; the syringe can then be removed and the fluid introduced by gravity. If a Luer-Kaufman syringe with a glass offset is used, the solution can be introduced immediately through the syringe itself.

By this method the intravenous administration to children of any age is greatly simplified; if arsphenamin can be given with so little danger, then certainly saline, glucose and other mild solutions can safely be used.

These modifications make the intravenous introduction of fluid comparatively easy; the child is disturbed only little, and a definite amount of solution may be given quickly, although the amount that can be given at one time is limited.

5. Intraperitoneal Injection.—This was first used in St. Bartholomew's Hospital and was introduced in this country by Howland. Blackfan and Maxcy have reported the successful employment of this method.

The instruments needed are a medium-sized intravenous needle, an infusion bottle and rubber tubing. The skin of the abdomen is carefully sterilized with tincture of iodine and alcohol. The skin and subcutaneous tissue are picked up between the thumb and forefinger, and the needle is introduced in an upward direction through the abdominal wall in the midline just below the umbilicus. Care must be taken to avoid piercing a distended bladder, and while there is also danger of puncturing the intestine, no record of this accident has come to my attention. In cases in which necropsy was performed there was found a small hemorrhagic area in the abdominal wall and peritoneum, but no injury of serious importance.

When the needle has passed into the peritoneal cavity, the solution is introduced by gravity. At first I used a Luer syringe; but later I found it much easier to employ the infusion bottle. I have always used warm physiologic sodium chlorid solution, of which from 100 to 250 c.c., in older children from 300 to 400 c.c., may be given every twelve to twenty-four hours, in fact, if no untoward signs develop, fluid may be given until the abdomen becomes slightly distended. However, the injection must be made slowly in all cases, and overdilatation of the abdomen must be avoided. After the operation, the abdomen is covered with a sterile dressing. It has been shown by the phenolsulphonephthalein test and by necropsy that from 40 to 60 per cent. of the fluid is absorbed in one hour. The remaining solution acts as a reserve, the gradual absorption of which explains the more protracted improvement as compared to results obtained by other methods.

We had used the other methods at the Infants Summer Hospital, but this year we chose the intraperitoneal route for children who had lost large amounts

of fluid by vomiting and diarrhea. It proved superior to all other methods because of the ease and rapidity of administration, the volume of fluid that can be given at one time, and the certainty that no fluid will be lost. The results from this treatment are remarkable; and although it has been used only in the most serious cases, the results have been most satisfactory.

The following case is reported to show that repeated injections may be made without injury to the intestine:

Rita C., aged 1 year, weighing 11¼ pounds, was admitted to the Infants Summer Hospital, August 18, with a history of vomiting and diarrhea for the previous ten days. She was born at eight months, the delivery being instrumental; the birth weight was 7¾ pounds. The child had been breast fed until the present illness when she was put on condensed milk.

On admission the child had a wasted appearance and was semiconscious. The physical examination revealed slight stomatitis, coldness of the extremities, weakness, and great loss of water from the tissues; the temperature was 101.6 F.; the pulse, 148. Stimulating treatment was at once instituted. On the first day she retained one-half ounce of rice water, vomiting all other fluids; on the second day seven stools were passed and very little fluid was retained. The feces contained blood and mucus. There was no improvement in the bowel condition on the third day, and the loss of fluid was producing great prostration. Since no results followed administration of fluid by rectum or the use of stimulants hypodermically, 100 c.c. of physiologic sodium chlorid solution were injected intraperitoneally, with favorable results. It was not until the thirty-fifth day of the disease that the child passed normal stools; even then the bowel condition was far from satisfactory. During this time there had been an average of seven mucous and bloody stools daily; in fact, many of the movements were thick mucus stained with blood. For days in succession she would take less than 1 ounce at a feeding, and vomited a great part of all fluid ingested. She failed to such an extent that it did not seem possible that she could live another day. The temperature ranged from 99 to 102.6, most of the time above 101 F. In all, ten injections of saline solution were made through the abdominal wall, ranging in quantity from 100 to 250 c.c., six being over 200 c.c.

The fluid carried the child over the critical days until the bowel condition began to improve. We had never before seen a child recover after so long and severe an illness. The recovery is evidence of the value of this method of treatment and of the safety with which repeated injections may be made through the abdominal wall.

SUMMARY

1. The administration of saline and other solutions is frequently of great value in carrying children over critical periods of illness, especially in diarrheas with marked loss of fluid.

2. When it is impossible to give fluid by mouth or rectum, intravenous or intra-abdominal injections are indicated. If puncture of the superficial veins proves difficult, the superior longitudinal sinus or the femoral vein may be selected.

184 Alexander Street.

Sanitation in Universities.—Environment plays an important rôle in disease causation and prevention. This is especially true of communicable diseases. It is most important to know and to regulate, so far as possible, the conditions under which students live, the food and water ingested, the air breathed, etc. The division of sanitation is therefore no minor part of a university health service, and ample provisions must be made for this branch of the work. The environment of the student, both on and off the campus, must be regulated and made as sanitary as possible.—John Sundwall, *Pub. Health Rep.*, Nov. 7, 1919.

Chief of Clinic, Gastro-Enterological Department, Jefferson Hospital;
Attending Physician, Methodist Episcopal Hospital

It is with reluctance that I am calling attention to a new tip for duodenal tubes because there are many excellent ones already on the market; but I feel sure that it will interest those members of the profession who are doing gastro-duodenal work because it possesses certain definite advantages over any other type with which I am familiar. Perhaps I might better say that it does away with certain disadvantages common to nearly all others.

All duodenal tubes are swallowed rather easily by most patients, but many patients encounter temporary difficulty when the tube is withdrawn from the duodenal zone to the stomach, and more especially difficulty when it passes the glottis on its upward journey, at which time cooperative swallowing control is required on the part of the patient. This applies particularly to all tips of the olive or ball type on account of the shoulder or collar on the proximal side of the tip. They go down easily, but they are much more likely to "hang" at the glottis coming up.

To obviate this difficulty I have been trying out, during the past year, a tip quite similar to that designed by Rehfuß,

Three styles of tip for duodenal tubes: A, new style tip with no shoulder or collar and with a long and serrated shank; B, ball type tip with objectionable collar and short shank, and C, olive type tip with objectionable collar and short shank.

but of elongated pear shape instead of olive shape. The tip is ground down to a tapering proximal end of the same caliber as that of the rubber tubing. Therefore, in withdrawing this tip, all obstruction at the glottis is done away with. All patients, especially those well "tube broken" to many varieties of tips, are unanimously in favor of this one; and after all it is the patient who can furnish the best endorsement in such a matter.

The second advantage of this tip lies in the fact that its shank is slightly elongated and slightly serrated so that the rubber tubing, even when old, will stick closely to this tip under a stout pull without the necessity of its being tied and knotted with a silk thread. The latter point seems to me a very objectionable feature; for these knots instead of getting softer after boiling become distinctly harder, and I feel sure in many cases they traumatize the gastric or duodenal mucosa, especially in the latter zone where the tube may be left in situ for many days for feeding purposes, because the duodenal lumen is comparatively small and the peristaltic action vigorous.

The only duodenal tube with which I am familiar that does not possess the disadvantages I have just stated is the one designed by Jutte. This tube, I believe, is the easiest to pass to the stomach or duodenum, and I still continue to use it very frequently for such treatment as transduodenal lavage; but I do not like it for duodenal feeding because the perforations at the tip of the rubber tubing are so small that they frequently become obstinately plugged with the feeding mixtures. And for the same reason, I have discarded the use of this tube in diagnosis on account of the difficulty of aspirating many catarrhal residuums: and especially have I had difficulty in draining the biliary tract on account of the heavy viscosity of many biles.

Another point worth mentioning in gastroduodenal work is that the tube should be fitted with a glass window situated from about 8 to 12 inches from the proximal end, instead of with the metal connections in common use, so that the aspirated material may be inspected before it reaches the aspirating syringe, vacuum bottle or collecting vessel. By this means, material of special interest may be segregated for special study. This is of paramount importance in gall-bladder and gallduct diagnosis.¹ A medicine dropper answers very well if the capillary tip is of the same caliber as that of the rubber tubing, or larger; or special small connecting glass tubes may be obtained from any physicians' supply house.

These tips may be obtained through the Physicians' Supply Company, Sixteenth and Sansom streets, Philadelphia.

1828 Pine Street.

CAUSTIC BURN OF THE EYE FROM INDELIBLE INK OR LEAD*

WILLIAM H. ELMER, A.B., M.D., ROCKFORD, ILL.

Though injuries to the eye from the introduction of indelible ink or indelible lead are not very rare, the recorded cases have not taken on the aspect of a caustic burn. Therefore this case is presented:

REPORT OF CASE

Oct. 13, 1919, Miss F. L., aged 20, waitress, complained of pain in her left eye, and said that some ink had entered it twenty-four hours before. She was unable to state how this had happened; she realized that something was wrong only by the symptoms she had suffered, and knew it was ink by the appearance of the eye.

Examination revealed R. V. 20/20, L. V. 20/30, tension 0, both eyes. The left lower lid was slightly swollen, and the palpebral and bulbar conjunctiva of the lower fornix was congested, chemotic, and stained an intense purple, the color of the common indelible pencil lead. The stain increased in intensity downward, and among the tarsal folds was a clean cut, almost black ulcer, as if a fragment of the lead had rested there and exerted its effect strongly at one point. With a probe, it was ascertained that the ulcer was quite deep, almost penetrating to the infra-orbital margin. Almost the entire conjunctival surface beneath the lower lid stained with fluorescein. The upper lid and underlying conjunctiva were negative. There was slight staining of the lower margin of the cornea; the iris was clear, and the pupil of moderate size, but it responded rather sluggishly to light. Examination of the media and fundus detected nothing further.

The eye was irrigated thoroughly with sterile water till the waste showed no color, and then as much as possible of some black granular matter on the ulcer was removed with wet applicators. Atropin, 1 per cent., and argyrol, 20 per cent., were used; and after the conjunctival sac had been filled with sterile petrolatum, a patch was applied and the patient was sent to the hospital for further attention. Petrolatum was used in the eye every two hours for the next day, at the end of which period, iritis was found to be setting in. Atropin was started immediately and used every four hours next day, with the petrolatum continued at two hour intervals. On the following day the pupil was well dilated; and the petrolatum having been discontinued for a short time, fluorescein showed epithelization to be taking place slowly; but the patient was complaining of pain over the left cheek bone, and there was intense tenderness over the left infra-orbital margin, and some swelling and redness. Nasal examination disclosed no indications of maxillary sinusitis, and further investigation by means of the roentgen ray was refused. Dry heat to the painful region was ordered, and atropin, argyrol and petrolatum were used three times daily. Slight adhesions that were forming were broken up with a

* From the "Johnson Clinic."

probe. On the third day epithelization was complete except for the ulcer and a slight area around it, the pupil remained dilated, congestion was subsiding, and the pain and swelling over the cheek had improved. On the fifth day, there was no staining with fluorescein, congestion was slight, the purple stain was disappearing, and the complicating symptoms had vanished, whereupon the patient was discharged, to report at the office next day. The appearance at this visit was almost normal, the dilated pupil, slight congestion, and purple discoloration alone remaining, so she was ordered to use a boric acid eye-wash and argyrol, 20 per cent., once daily, and to report again a week later. When last seen, October 25, the eye appeared quite normal with 20/20 vision in each eye. A small scar was visible at the site of the ulcer, but there was no deformity from cicatricial contraction.

COMMENT

How this caustic substance could have entered the eye was not ascertained. Cosmetics for eyebrow and lid margin use might have been the source (and the patient was strangely reticent about the whole affair), but such accidents have been known to occur from pencil lead, though the effects have not been as violent as in this case. A case is quoted in a personal communication to me as having occurred from this source, the same purple stain having resulted, but with no ill effects and with complete recovery in twenty-four hours after use of 1:3,000 mercuric chlorid ointment.

The complicating pain and tenderness over the infra-orbital margin seem to me to have been due to a moderately severe periostitis from penetration of the irritant through the tissues.

DEMONSTRATION OF TUBERCLE BACILLI IN THE SPINAL CORD OF A PATIENT SUFFERING FROM TUBERCULOUS MENINGITIS*

HERMAN L. KRETSCHMER, M.D., CHICAGO

Urologist, Presbyterian Hospital; Genito-Urinary Surgeon, Alexian Brothers Hospital, and Assistant Professor of Surgery, Rush Medical College

REPORT OF CASE

History.—J. F. K., a private, aged 19, admitted to the medical ward of U. S. Army Debarkation Hospital No. 5, Feb. 2, 1919, stated that while on the transport that brought him back to this country from overseas he had an acute attack of bronchitis, which was associated with severe headache, and pains in the chest, back and bones. A few days prior to his admission to the hospital he had suffered considerably from gastric distress.

Physical Examination.—The patient appeared very restless and nervous, and seemed excitable. The head, neck and scalp were negative. The pupils were equal and reacted to light and accommodation. There was no increased intra-ocular tension and no rigidity of the neck.

Examination of the lungs disclosed a small area of impaired resonance at the base of the lower lobe of the left lung, posteriorly. At the end of inspiration, a few fine subcrepitant râles were heard. There was a small area of bronchophony. Examination of the heart was negative.

The clinical diagnosis made at this time was a left bronchopneumonia following influenza.

Clinical Course.—From the day of admission until February 4, there was no change in the patient's condition. February 4, he complained of slight pains in the back of the head.

Urinalysis made, February 3, revealed a specific gravity of 1.030, some albumin, but no sugar or casts. A blood examination made on the same day revealed 12,200 leukocytes.

February 5, the patient still complained of headache, and examination disclosed the presence of a slight amount of rigidity of the neck. As a result of this examination, a tentative diagnosis of tuberculous meningitis was made, and a

lumbar puncture was immediately performed. The fluid withdrawn was slightly turbid. After the lumbar puncture, the headache was relieved.

Examination of the cerebrospinal fluid, February 5, gave a cell count of 222. Smears failed to show the presence of organisms, and the culture remained sterile. The Wassermann reaction of the spinal fluid was negative, and no tubercle bacilli were found in the smears. Examination of the blood disclosed 9,200 leukocytes.

February 7, a second lumbar puncture was performed. This time the fluid spurted from the needle and appeared to be under pressure. Thirty c.c. of fluid were withdrawn. Smears failed to demonstrate the presence of organisms, and the cultures remained sterile. No tubercle bacilli were found, and the Wassermann reaction was negative. No sugar was found in the fluid. Differential leukocyte count revealed 75 per cent. lymphocytes and 25 per cent. polymorphonuclears.

By February 8, the muscular rigidity had very materially increased, and Kernig's sign was present. February 9, the patient developed complete retention of urine, so that he was unable to void and had to be catheterized.

Urinalysis, February 9, demonstrated the presence of albumin in moderate amounts, and a few pus cells and a few casts. The urine showed a pure culture of *B. coli*.

February 10, the patient was very cyanotic and was confused a great deal, mentally. A lumbar puncture was performed, and 100 c.c. of fluid were removed. The cultures remained sterile, and no organisms were found in the smears. No tubercle bacilli were found, and the Wassermann reaction was negative.

February 11, the patient died.

Necropsy Findings.—Necropsy was performed two hours after death by First Lieut. Paul H. Christian.

When the brain was removed, a fair amount of clear straw-colored fluid escaped from beneath the meninges. A few fresh adhesions were found at the base of the brain; otherwise its appearance was normal.

Examination of the spinal cord revealed no adhesions between the cord and bony structures. When the meninges were removed, however, a few slight adhesions were observed between the cord, covering a space about 2 cm. in length, beginning at the lumbar enlargement and extending upward. In this area were also found slight subdural hemorrhages, and petechial hemorrhages were found in the cord substance.

The right lung appeared normal. The left lung showed evidences of resolution in one or two areas. In the upper lobe, posteriorly and near the base, there was a spot about 4 cm. in diameter that was undergoing resolution.

The heart was contracted, and there was no evidence of any inflammatory condition. The valves were apparently normal.

The liver, spleen, kidneys and pancreas presented no unusual pathologic condition. The bladder was dilated, and contained about 800 c.c. of fluid.

Postmortem diagnosis was bronchopneumonia undergoing resolution, and a tuberculous meningitis.

Microscopic Examination.—The section from the base of the brain showed great round cell infiltration of the pia, and this infiltration was especially marked about the blood vessels. There were also in the pia areas of granular necrosis, with much nuclear debris: these areas were occasionally surrounded by typical epithelioid cells. No giant cells were seen. Perivascular round cell infiltration was also seen in the cortex.

In the section from the lumbar portion of the cord there were dense, small round cell infiltration of the meninges, and large areas of caseation, surrounded by epithelioid cells. In the adventitia of many of the blood vessels in the pia, there was a definite formation of tuberculous tissue.

In the sections stained for acid fast bacilli, there were found a few typical acid fast bacilli in the sections from the cord. No bacilli were demonstrated in the sections from the brain.

The microscopic diagnosis was tuberculous meningitis.

USE AND ABUSE OF CATHARTICS*

(Continued from page 177)

CALOMEL CATHARSIS

Mild mercurous chlorid is the typical cholagogue cathartic, a term that might be applied to those agents that have a tendency to produce particularly dark or bile-colored bowel evacuations. That certain cathartics, notably calomel, have such action, is a well established clinical observation. Trouble arose when this foundation of fact was left behind and fancy was permitted to assign to these agents a special action on the liver. Nothing seemed more logical than this supposition, though, it appears, nothing is farther from the truth.

It took much investigation and controversy to establish the fact that only a small number of substances increase the secretion of bile and that this does not include any one of the cathartics. The cause of the dark color of the stools following the use of many cathartics is evidently a mechanical one, a more rapid sweeping of the contents out of the intestine, so that there is less time for reabsorption of bile and change in the color of bile pigment. In the case of calomel, to this must be added the fact that grayish-green stools occur even when no bile enters the intestine, owing to the formation of colored mercury compounds, such as sulphid and oxid. A third factor, which also might have something to do with the bile colored purging produced by calomel, is its preservative effect on bile pigment, demonstrable in the test tube, due to inhibition of putrefactive processes responsible for conversion of bile pigment into fecal pigment.

MODE OF ACTION

Calomel, being insoluble in the mouth and the stomach, passes through without affecting them in transit. Indeed, one of the chief advantages—as well as disadvantages—of calomel is its inoffensiveness to palate and stomach. It is one of the few purgatives that can be given in spite of nausea and vomiting. At times it stays in the stomach when nothing else will. On the other hand, the ease with which this subtle poison can be given invites its abuse, especially in children.

As soon as the calomel enters the intestine, it is attacked by the alkaline pancreatic and intestinal juices, which decompose it into mercury and yellow mercuric oxid. The latter dissolves slowly and incompletely in the alkaline intestinal fluid. The small quantity of mercuric ions thus liberated excites peristalsis and, at the same time, inhibits absorption of fluid. These effects are so much greater in the small intestine than in the colon that calomel is unreliable as a cathartic. The abnormal amount of fluid in the large intestine may be completely reabsorbed, giving rise to

diuresis instead of catharsis, unless this reabsorption is inhibited by a saline purgative. Hence, administration of a saline cathartic in connection with calomel catharsis has come to be an established custom. As calomel acts slowly, requiring from ten to twelve hours, while the salines produce their effect in about two hours, the two agents are usually given with an interval of eight or ten hours between them: generally, the calomel at night, and the saline in the morning.

Unfortunately for its use as a cathartic, some of the calomel becomes absorbed, giving rise to the danger of mercurial poisoning, which is much more influenced by the length of time the mercury stays in the bowel than by the size of the dose: for, when the calomel is promptly swept out of the intestine, it is safe in almost any dose; while a small amount may lead to poisoning, if, by reason of intestinal obstruction or other delay in evacuation, the calomel becomes absorbed to any great extent. Another factor that influences absorption is the presence of solvents. Particularly objectionable is iodid, which, even when taken separately or previously, changes calomel into mercury (metallic) and mercuric iodid and readily dissolves the latter. This change results in a great increase in local irritation—wherever the calomel comes in contact with the iodid—and in greater absorption of mercury. Bromids and alkalis are less obnoxious in conjunction with calomel. Alkali, in the form of sodium bicarbonate, is frequently combined with calomel on the supposition that this increases the efficacy of the latter. The increase in solubility of calomel under the influence of chlorid or hydrochloric acid, under the conditions that prevail in the system, is so slight as to be of no toxicologic importance. An investigation by the A. M. A. Chemical Laboratory¹ showed that the combination of calomel with antipyrin becomes dangerous in the presence of sodium bicarbonate, as, in such a case, from one sixth to one fourth of the calomel may become converted into a soluble mercury salt. The idea that acid drinks, such as lemonade, should be avoided in conjunction with calomel has been shown to be erroneous.

CALOMEL POISONING

It is not necessary, in this place, to draw the picture of calomel poisoning. Suffice it to say that this condition affects most especially the two ends of the alimentary tract: the mouth and the colon, and that the kidney is next in order. In the mouth, it produces ulcerative stomatitis, which somehow is connected with the presence of teeth, especially carious teeth. Toothless infants do not develop it. The necrosis starts at the dental margin of the gums and where the teeth are in relation with lips, cheek and tongue. The fact that mercurial stomatitis is characterized by a pathologic condition similar to that of ulcerative stomatitis and Vincent's angina should render calomel contraindicated in the presence of these conditions. If a patient has ever been salivated, calomel should not be used again, for he is liable to show exceptional susceptibility. As mercurial colitis is characterized by a symptomatology and even a pathology much like that of dysentery, one should be cautious, when using calomel in dysentery or enterocolitis, not to confound the symptoms produced by calomel with those of the disease. In these

* This is the fifteenth of a series of articles on the pharmacology, physiology and practical application of the common laxatives and cathartics. The first article appeared October 18.

1. The Incompatibility of Antipyrin, Calomel and Sodium Bicarbonate, J. A. M. A. 56: 287 (Jan. 28) 1911.

conditions, its continued administration should certainly be avoided. As mercury has a great affinity for the kidney, calomel should not be employed, excepting with the utmost precautions, as a cathartic in kidney disease, unless it be in a syphilitic. In certain cases of nephritis, even a small dose of calomel may precipitate uremia.

As calomel is so unreliable a cathartic that it needs be associated with other purgatives to secure its evacuation, as it is liable to act as a poison, and as we have an abundance of satisfactory nontoxic cathartics, the use of calomel as a mere purge is unjustifiable. Of course, in a patient suffering from syphilis it might be the cathartic of choice. It might also be of special value as a purge in the presence of vomiting. Calomel should never be given without other indication than simple constipation. It is absolutely unsuitable for self-medication by the laity.

The main reason for its popular use as a purge is its alleged action as an intestinal antiseptic. That it is not an intestinal disinfectant is generally admitted, nor has its action as an intestinal antiseptic been definitely proved.

INDICATIONS

As calomel is so inoffensive to the stomach, it is the purgative *par excellence* in the presence of nausea or vomiting, provided one is certain that intestinal obstruction does not exist.

Calomel finds its classical employment in "biliousness," a syndrome that follows indiscretions in diet, whether it be excessive indulgence in food by a healthy person or mere relative excess in an invalid. This condition is characterized by yellowish coated tongue, fetid breath, anorexia, headache, lassitude, subicteric tinge of skin and conjunctivae, and highly colored, scanty urine. But the chief indication for it is believed to be the presence of clay-colored stools, whether there be constipation or diarrhea; and, for reasons given above, it will certainly change the color. Whatever the exact pathology of the condition, free purgation is usually followed almost immediately by amelioration of symptoms; and calomel-saline purgation is believed to be more efficient in this condition than the use of other evacuants. Indeed, its very efficiency is a danger: for it encourages the patient to continue in his overeating, knowing that he can escape the punishment or greatly mitigate it by his dose of calomel. This abuse of the digestive and eliminative organs cannot but lead in time to chronic degenerative changes, insidious in onset but incurable when present. How much better for an individual inclined to "biliousness" to limit his food intake to his digestive capacity than to gorge himself with food only to purge himself of the excess after it has commenced to harm his system. In view of the remarkably slight intestinal irritation produced by a therapeutic dose, calomel is often employed in summer diarrhea and in dysentery. In these conditions, castor oil is preferable, unless coexisting nausea or vomiting renders the administration of the oil impossible. For reasons previously given, it should be used merely as an initial course. Prolonged administration might increase the damage.

Calomel is employed, by many physicians in a routine manner, as the initial purge in acute febrile conditions of all kinds. Experience in such cases, both with and without calomel, does not demonstrate any difference

in favor of those patients that had received calomel. One sees, on the other hand, every now and then—fortunately but very rarely—cases of mercurial stomatitis as the result of this practice, most commonly perhaps among patients who have had a succession of different medical advisers and a succession of "initial" doses of calomel. Hence, when one is not the first to be called on the case, it is best to omit the dose of calomel; and it would probably be just as well to omit this dose on the principle of *nil nocere* in other cases likewise.

ADMINISTRATION

So called "broken dosage" is, at present, the method of choice in the giving of calomel. The advantage claimed for it is a greater effect from a total small dose than could otherwise be obtained, each instalment coming in contact with fresh portions of solvent. At the same time, there is less danger of poisoning if the total dose is retained and absorbed, than if a dose of 0.60 gm. (10 grains) were given. Whether the total dose of from 0.06 to 0.12 gm. (1 to 2 grains) is given in portions of 0.006 gm. ($\frac{1}{10}$ grain), 0.010 gm. ($\frac{1}{10}$ grain) or 0.030 gm. ($\frac{1}{2}$ grain) at intervals of fifteen minutes, thirty minutes or an hour is chiefly a matter of convenience; though, it is claimed that, in the presence of vomiting, the smaller dosage and longer intervals serve best. The rule is sometimes given that the dose of calomel for children should be once or twice as many centigrams ($\frac{1}{10}$ grain) as the age of the child in years. In practice, however, but little difference usually is made between the dose for the child and the dose for the adult; for, in either case, only that portion of the dose becomes active that is dissolved; and this depends on the amount of alkaline digestive secretion, which is proportionate to the size of the individual. Nevertheless, some such rule as that given prevents the administration of large excess; provided, of course, the adult dose is not exceeded, which will be reached according to the rule at the age of 3 or 6.

Owing to the smallness of the dose and the heaviness of the calomel, a diluent is necessary in prescriptions for calomel powders. Sugar, sugar of milk, or sodium bicarbonate are the usual diluents.

	Gm.
B. Mild mercurous chlorid	0.06
Sugar of milk	0.24
Mix and divide into four powders.	
Label: One every half hour.	

For children, sugar is the preferable diluent. However, the most elegant way of prescribing calomel is in the form of sweet tablets, each containing 0.006 gm. ($\frac{1}{10}$ grain) and up, which are now marketed by nearly all manufacturing pharmacists.

(To be continued)

Group Medicine.—The experience of military service will have rendered thousands of physicians familiar with methods of organization and accustomed them not only to the treatment of individual patients, but to coordination of work with other doctors. The return of these physicians to private life may well be occasion for stimulating the organization of medicine and for helping the institutions in which group medicine is practiced. Members of the medical profession, men who are concerned with public health work, or with the administration of hospitals and dispensaries, should not permit the leadership in developing medical organization to pass out of their hands. Group medicine is a necessary progressive step in the practice of medicine for the public service.—M. M. Davis, *Am. J. Pub. Health* 9:362, 1919.

SATURDAY, JANUARY 24, 1920

SPIROCHETE TRANSMISSION IN RAT-BITE FEVER

The demonstration that dangerous spirochetes may be present in rats and become the etiologic agent in the so-called rat-bite fever of man and animals is only a few years old.¹ Meanwhile the widespread distribution of the micro-organism in various parts of the world, including cities of the United States, has been ascertained by bacteriologic examination of rats caught at random.² The current belief is that the spirochetes find their way into the excretory ducts of the salivary glands and the tubules of the kidneys, and that the infection in true rat-bite fever comes through the saliva of the biting rodent. This assumption has been assailed of late, however, by a group of investigators at the Kitasato Institute for Infectious Diseases in Tokyo.³ According to them, in the infected wild rat, albino rat and guinea-pig, the spirochetes of rat-bite fever, in the early stages of the infection, are detected principally in the blood; but after two weeks a large number appear in the connective tissues, and as time goes on this number is gradually increased. That is, this spirochete is always distributed numerously in the subcutaneous and submucous tissues of the eyelids, lips, bridge of the nose, and tongue, and is especially abundant in the reticular connective tissues of the vascular sinus surrounding the follicle of the tactile hair of the upper eyelids and lips. It is also usually, if not always, found abundantly in the capsules of the salivary and lymph glands, in the heart wall, in the adventitia of the aorta and large arteries within the visceral organs, and sometimes in the endocardium of the heart. It can also be detected in the spleen, the liver, the suprarenal glands, the kidneys, the parenchyma of the salivary and lymph glands, etc. The Japanese investigators assert that the spirochete is neither excreted through

the saliva from the salivary glands nor mixed into the saliva through the normal mucous membrane of the mouth cavity from its submucous source. Furthermore, the excretion of the organism in the urine was found to be comparatively rare. The spirochete has never been detected in the intestinal contents of wild rats and guinea-pigs or in the bile of guinea-pigs.

How, then, are we to suppose that the spirochete finds its way into the organism that it attacks? The more recent experiments do not favor the view that this spirochetosis can spread by mere contact, or that its distribution is facilitated by such skin parasites as fleas and lice. Attempts to produce infection by instilling contaminated blood into the eyes of susceptible animals were unsuccessful in securing transmission through the intact conjunctiva; and the undamaged mucous lining of the alimentary tract also appears to be a barrier to the spirochetes introduced by mouth. The few positive infections may be attributed equally well to abrasions of the mucous membranes which permitted an invasion of the tissues.

To explain the exit of the spirochete from its source in the host, if it does not pass out through the saliva, Kusama, Kobayashi and Kasai³ assert that the infected wild rat, and also the infected guinea-pig, usually become very irritable and furiously bite any objects coming in their way, often suffering an abrasion and even bleeding in the lips or gums. The spirochete is then given an opportunity to escape from the submucous tissue, or the circulating blood, through the defective point in the mouth. It becomes possible, therefore, that the spirochete may be thus transferred by the bite of an infected rat to the body of a healthy rat or even a human being.

LOW BAROMETRIC PRESSURE AND CHANGES IN CIRCULATION

Mountain climbing and likewise the more easy ascents to mountain heights by the modern alpine railways are not infrequently attended with symptoms of malaise. Experiences of this sort long ago emphasized the fact that high altitudes or low barometric pressure may interfere with the normal workings of the human machine. There was a time not long since when the physiology of altitude had little more than academic interest. The modern conquest of the air by man has brought about a new attitude. As the physiologic experts in military aeronautics have lately pointed out,¹ the purely scientific aspects of life under conditions of low barometric pressure are themselves deserving of careful investigation. The fact that altitude plays a part in therapeutics and forms a feature of climatology, as applied by medicine, furnishes another reason why the subject should be placed on a rational basis, while the coming into prominence of aviation, which requires

a man to ascend into the air as the bird, frequently to moderate and sometimes to great altitudes, furnishes a third reason why we should know what constitutes fitness for life in rarefied air.

Certain effects of transferring man to high altitudes are already well appreciated. The partial pressure of oxygen decreases as the barometer falls in ascending into the atmosphere. Consequently the eminent French physiologist Paul Bert predicted more than forty years ago that the blood of persons and animals living at high altitudes would be found to have a greater oxygen-carrying capacity than that of corresponding individuals living at lower levels. This prediction has frequently been verified. Thus, the red corpuscles charged with the function of binding and transporting oxygen vary in numbers at sea level between 4.5 and 5.4 millions per cubic millimeter; at Colorado Springs, altitude 6,000 feet, between 5.5 and 6.3 millions; and on Pike's Peak, altitude 14,110 feet, between 6 and 8.2 millions. The percentage of hemoglobin, the compound concerned in the oxygen transport, has simultaneously been shown to increase at Colorado Springs at least 10 per cent. on the average above the content at sea level; while at Pike's Peak an increment of 44 per cent. has frequently been noted. The percentage of oxygen capacity in the blood at sea level varies between 17 and 18.7; at Colorado Springs, 20 and 21.7; and on Pike's Peak, approximately 27.4. In general, for every hundred mm. fall in atmospheric pressure there is an average rise of about 10 per cent. in hemoglobin, and this rise is approximately the same for women and men.

The conventional records have been obtained from observations made after hours or even days of exposure to the effects of high altitude and lowered partial pressures of oxygen in the atmosphere. The aviator makes his transitions with incomparably greater speed. Mountain ascents, even when made passively by railway or motor, are slow—8,000 feet in an hour and a half or longer—as compared with altitude flights in an aeroplane. Can the aviator, who ascends with much greater speed and has already reached heights beyond that of the highest mountains on the globe, benefit from any compensatory physiologic reactions such as have been described? To this question the medical research laboratory of the air service at Mineola, N. Y., has contributed some answer.² The blood changes were studied in men subjected to lowered barometric pressures or to low oxygen, 10 per cent., for intervals not exceeding two hours. The changes in a pressure chamber were made at a rate that would be comparable to ascending in the air at the rate of 1,000 feet a minute. The altitudes employed were 425, 395 and 380 mm. of mercury, which are the pressures ordinarily encountered at 15,000, 17,000 and 18,000 feet, respectively. The blood changes were definite in thirty-five trials, or

78 per cent., of all examinations made by Gregg, Lutz and Schneider at Mineola. The majority of the men required between forty and sixty minutes for the increase to become definite; 13 per cent. showed a well defined increase within twenty-six minutes. In the experiments with 10 per cent. oxygen, 57 per cent. gave the increase in hemoglobin. In fifteen cases in which the erythrocytes and hemoglobin were determined, corresponding changes occurred in both; 66 per cent. were positive. The erythrocyte increase ranged between 3.8 and 20 per cent.; the hemoglobin, between 3.2 and 9.8 per cent. These results are not due to barometric pressure per se: they represent the response to lowered oxygen pressure in the environment, however this may happen to arise.

Obviously, under conditions of oxygen shortage, tissues may be better supplied with this element not only by an increase in corpuscles which carry it but likewise by a more efficient circulation. A more rapid blood flow also represents a form of compensatory reaction to the oxygen deficiencies at high altitudes; and it has been observed to occur quite independently of any added physical exertion or other extraneous influences, such as fatigue or cold. In general, it may be said that the heart works at an increased rate in all postures at the high altitude. The amount of increase in the pulse rate varies in different persons. Some men will show at the high altitude, such as 14,000 feet, an acceleration of only a few beats over the low altitude rate, while others show an increase of 10 or more beats per minute. Lutz and Schneider,³ likewise working at the laboratory of the air service at Mineola, have found that the heart rate responds to slight changes in oxygen tension. The acceleration in the majority of men examined began between oxygen partial pressures of 113 and 128 mm., corresponding to barometric pressures of 542 and 610 mm. In at least 25 per cent. of all cases, the first response occurred at oxygen partial pressures of about 137 mm. or less, corresponding to a barometric pressure of 656 mm. (4,000 feet). The initial response occurred at about the same oxygen tension each time a person was exposed to a decreasing oxygen tension by the several methods used. The systolic blood pressure maintained its normal level in the majority of cases.

It is not easy to understand how compensatory responses in the nature of rapid increments in the number of red corpuscles, whereby the unit volume of blood can carry more oxygen than normally at a given oxygen pressure, occur in such short periods of time as those involved in an hour's flight. It can scarcely be supposed that the cells are created anew thus rapidly in the organism. There is little evidence that the increased number of corpuscles is due solely to an actual concentration of the blood by loss of water. For the present it seems more likely, as Schneider and

2. Gregg, H. W.; Lutz, B. R., and Schneider, E. C.: The Changes in the Content of Hemoglobin and Erythrocytes of the Blood in Man During Short Exposures to Low Oxygen, *Am. J. Physiol.* **50**: 216 (Nov.) 1919.

3. Lutz, B. R., and Schneider, E. C.: Circulatory Responses to Low Oxygen Tensions, *Am. J. Physiol.* **50**: 228 (Nov.) 1919.

Havens⁴ have suggested, that the "rapid increase is brought about in part by throwing into the systemic circulation a large number of red corpuscles that under ordinary circumstances at low altitudes are sidetracked and inactive, and in part by a concentration resulting from a loss of fluid in the blood."

THE SAFEGUARD AGAINST BACTERIA IN THE UPPER AIR PASSAGES

It has been assumed, until quite recently, that healthy and intact skin and mucous membranes are practically impenetrable to bacteria that may lodge on them. The mechanical protection offered by the surface covering of the deeper tissues and vessels within them is, however, known to be lost when bruises or contusions destroy the outer layers or otherwise alter their normal continuity. Zinsser⁵ has pointed out in this connection that the defense of the intact mucous membranes is by no means unassailable. While many kinds of organisms can be implanted on mucous membranes with impunity, a number of others may cause local inflammations thereon and may, furthermore, pass through them into the deeper tissues and thence into the general circulation. In illustration of this Zinsser states that gonorrhea is ordinarily a disease of implantation on a mucous membrane, and that diphtheria bacilli and streptococci give rise to a localized disease on the pharyngeal and nasal mucosae, the latter germs not infrequently penetrating from the initial point of lodgment on the mucosa into the deeper tissues and the blood stream, causing septicemia or bacteremia. Perhaps local physiologic or functional injury, such as congestion or catarrhal inflammation without demonstrable lesions, is sufficient to permit penetration by micro-organisms.

Latterly the membranes of the pharynx and adjoining regions of the nose and throat have become centers of great interest in the investigation of avenues of entrance for certain bacteria. The upper respiratory tract has been considered not only as a portal of entry but also as a site of persistence for the virus of some of the most serious diseases. Before the real significance and rôle of the mucous membranes there involved can be adequately comprehended, it will be necessary to learn much more than is now known regarding the factors that determine the survival of bacteria in the nasopharynx. An attempt in this direction has recently been reported by Bloomfield⁶ from the Medical Clinic at the Johns Hopkins Hospital. Large numbers of an easily recognizable nonpathogenic organism, *Sarcina lutea*, were introduced on the mucous membranes. It was usually impossible, even after a short period of time, to recover the sarcinae swabbed in large amounts on the tongue, nasal mucosa,

or into the crypts of the tonsils. Disappearance from the nose was somewhat slower than from the other sites; yet in only one instance could any of the organisms be recovered in twenty-four hours, and in no case after two days. Such findings testify to the tendency to rapid disappearance of the introduced foreign micro-organisms; and as the culture doses were vastly greater than those involved in any natural infection, the results, says Bloomfield, indicate the remarkable efficiency of the mechanism present in the upper air passages for disposing of the organism investigated in his studies.

There is reason to assume that this protective function of the areas involved is not necessarily simple or uniform in character. The possible flushing action of the secretions and the ejection of them in various natural ways from the nose and mouth represent mechanical factors. The possibility of chemical bactericidal action on the part of the secretions is also to be reckoned with. Finally, one must take into consideration biologic modes of resistance, such as phagocytosis or the effect of normal mouth bacteria on the invader. From his initial investigations with the single species mentioned, Bloomfield tentatively attributes the effectiveness in the disposal of the micro-organisms to a prompt and marked bactericidal effect exerted by the saliva and mouth secretions. This seemed to be independent of the bacteria normally present in the saliva. The reaction of the mouth secretions and mechanical cleansing played little if any part. It will be interesting to learn more about the safeguards against more virulent organisms and why they break down or fail in certain cases.

Current Comment

VACCINATION WITHOUT SCAR

An ancient joke relates that a "chorus lady," requiring vaccination, insisted that it be done so that the scar would not show. As a result, she took the virus in a spoon. It now appears that there may be another way of avoiding the scar without resorting to a spoon, viz., by hypodermic injection. During the last four years Major Goodall¹ of the Canadian Army has been experimenting with such a method. After using it on 6,000 soldiers and children he claims these advantages: (1) the absence of an open wound subject to infection; (2) the ability to dispense with dressings; (3) the high percentage of "takes"; (4) the comparative mildness of the local and systemic reactions; (5) the rapidity, and (6) the great ease with which it can be done in children. There were no accidents in his series. One man had a small slough which later healed over without any difficulty, and a few others had badly swollen arms. The advantages of such a method, if perfected and found reliable, are so obvious that it is not surprising that others have experimented with it in the past. Chauveau was probably the first, in 1886-1887, to show that it could be used in animals and in man. He tried

it also intravenously. It would seem from the experiments of Kraus and Volk² that Goodall might have lessened the severity of his reactions by using one thousandth of the dose. As would be expected, only very small amounts of the virus are needed for the subcutaneous injection. Casagrandi and later Knoepfelmacher showed that enough of the virus passes through a Chamberland candle to permit the use of the filtrate for subcutaneous vaccination. The literature is summed up by Knoepfelmacher,³ he was not satisfied at that time that the immunity conferred with this method would be as lasting as that with the old. In view of the importance of the suggestion, it is desirable that two questions be settled: first, whether or not the method actually produces an immunity, and second, the permanency of the immunity.

THE LESIONS OF TYPHUS FEVER

After death from typhus fever there are no constant characteristic lesions visible to the naked eye. The rash may have faded, and the organs, in uncomplicated cases, may show only congestion. It follows that an anatomic diagnosis of typhus fever can be made only on the basis of microscopic studies, if at all. Recent investigations summarized by Nicol⁴ and extended by him through the systematic microscopic examination of material from a large number of cases of typhus fever in which death occurred in all stages of the disease, have shown definitely that typhus exanthematicus is to be regarded as a systemic disease of the smaller arteries and the capillaries. There are necrosis and proliferation of the endothelium, associated with perivascular infiltration of leukocytes and other cells, especially in the skin and the central nervous system, and, to a less degree, the myocardium and practically all the other organs. The medulla, particularly about the olivary bodies, seems to be a favorite seat for this process, which sometimes may pass into a hemorrhagic encephalitis. Usually these characteristic arteriolitic and periarteriolitic foci disappear if the patient survives, but small scars may result. The localization of the changes in the medulla and upper part of the cord would seem to explain such symptoms as disturbances of deglutition, respiration and circulation, and no doubt death often results from lesions in the central nervous system; in cases of sudden death, lesions of the myocardium may be the cause. In about half of the cases complications, chiefly pneumonia, appear to determine the fatal outcome. Of the secondary invaders, streptococci are the most important. The demonstration of a widespread, focal arteriolitis and periarteriolitis in typhus fever is of great interest and value not only because it gives a better insight into the nature of the disease and the causation of the symptoms but also in that it provides new and important means for recognition of the disease in isolated or obscure cases referred to the pathologist for diagnosis by postmortem examination. We know that typhus may occur in cities like New York; and in

cases of death from what seems to be acute infection without any definite gross lesions, a thorough microscopic examination, with the vascular lesions of typhus in mind, would seem to be highly desirable.

AMERICAN JOURNAL OF THE MEDICAL SCIENCES—ITS CENTENNIAL

One hundred years have passed since the appearance of the first number of the *American Journal of the Medical Sciences*. Like the centenarians whose pictures appear in the daily press it is still going strong, with eyesight undimmed and digestion unimpaired. When interviewed as to the causes responsible for its long life it responded:

The *Journal* has been instrumental in molding medical thought not only here but also abroad, for being, with one exception, the oldest medical periodical in the English language it has been able to play a leading rôle in bringing before the profession of other lands the medical contributions of this country. Those who today guide the destinies of the *American Journal* are keenly aware of the heritage that is theirs and the responsibilities that it entails. It will ever be their earnest endeavor to maintain the high ideals in medical journalism for which this publication has so long been conspicuous. . . . They aim to make the *Journal* of the future the same honest, scientific, helpful periodical that it has been in the past.

We congratulate this centenarian on its high ideals and its enviable record: It has recorded the achievements of a century of American medicine — something certainly to be proud of.

DIAGNOSTIC VALUE OF EXAMINATION OF THE SPINAL FLUID

Since Quincke first introduced lumbar puncture, a very considerable development has taken place in the methods of examining the cerebrospinal fluid obtained by this procedure. At present, as Solomon¹ points out, there are five methods of examination in common use. These are the Wassermann reaction, tests for an increase in albumin, tests for globulin, the colloidal gold test of Lange, and the cell count. As these different tests have been developed there has always been a tendency on the part of their discoverers to herald them as more or less specific in character. Since the opening of the Psychopathic Hospital in Boston, a large series of spinal fluids have been examined by these different tests, and Solomon's article summarizes the results of this experience. There are two main conclusions to be drawn from his work: first, that the Wassermann reaction in spinal fluid is pathognomonic of neurosyphilis, although it may occasionally be absent in such cases; and second, that the other tests mentioned are not pathognomonic tests but are indicative merely of some inflammatory process involving the central nervous system. The analysis of the results obtained at the Psychopathic Hospital makes it clear that, with the exception of the Wassermann reaction, none of these tests, either singly or in combination, are characteristic of any one disease. It does not seem to matter whether the process is a meningitis, an encephalitis, a tumor with sympathetic meningitis,

inflammation following a vascular insult or a trauma, or a disease like multiple sclerosis. The result, so far as the changes in the spinal fluid are concerned, is essentially the same, namely, one or a combination of the reactions mentioned is produced. In one case, only pleocytosis may be present; in another case, the colloidal gold reaction may be positive and the other tests negative; in still other cases, combinations of these reactions occur. The examination of the spinal fluid is of such great value as a diagnostic aid that it is important that its limitations should be recognized. As Solomon points out, no spinal fluid can be said to be negative unless all of these different tests have been carried out. It is to be anticipated that further refinements in the examination of the spinal fluid will be developed; but it would seem from these studies that at the present time we can deduce from the examinations mentioned that a patient is suffering either from neurosyphilis or from some other inflammatory condition of the cerebrospinal system. In cases in which added elements like bacteria are present, the specific cause of the inflammation can frequently be detected; and this is true not only of acute infections but also of a large proportion of cases of tuberculous meningitis.

THE DIET IN PREGNANCY

In 1889, Prochownik recommended a "dietary for the purpose of avoiding the necessity of premature labor." He concluded that it is possible, through dieting the mother, to limit the weight of the child, and even retard the ossification of its bones. Unfortunately, his statements never seem to have been adequately confirmed. Recently Ehrenfest¹ analyzed the original paper of Prochownik. As a result, he believes that the author selected his cases in such a way that an especially favorable impression is produced. A survey of obstetric literature since Prochownik's original publication indicates that his views have received considerable attention, but the discussions are either quite neutral, or else the authors condemn Prochownik's views unqualifiedly. The few animal experiments available also offer no good evidence for the limited dietary. From the biologic point of view, present conceptions are that the fertilized ovum is an individual organism controlled by the placenta, an organ endowed with an active vitalistic function securing the substance essential for the development of the fetus from the maternal organism. It is also pointed out that the size of the fetus, including its general skeletal development, weight and length combined, is of more importance in the mechanism of birth than merely the weight alone. As a result of analysis from all these points of view, Ehrenfest concludes that the pregnant woman should not be permitted to eat to excess by responding, without restrictions, to the increased food desire created by the food demands of the fetus. It is his belief, however, that pregnancy causes an increased demand for food, which should be given in the form of nutritious, easily digestible substances. In the Prochownik diet, proteins are substituted for carbohydrates, and the

water intake is greatly reduced. Obviously, such a diet must be very carefully controlled and supervised, since it may actually be responsible for toxemic conditions, far more serious than any increased weight of the fetus. The adoption of routine treatments on the basis of *a priori* reasoning alone is not scientific medical practice. The question is one capable of easy proof by scientific research in any good hospital.

Association News

THE NEW ORLEANS SESSION

New Orleans and the American Medical Association

The *New Orleans Medical and Surgical Journal*, in its current issue, contains an editorial on the coming annual session of the American Medical Association, to be held in New Orleans, April 26 to 30. It says:

"Many remember New Orleans at the time of the 1903 meeting. The glamor of a Latin city, rough jeweled by modern civilization, set apart among the traditions of a people, still mourning its chapters of sad experiences of most a century and hard to rouse. The spirit of hospitality still alive, and ready to welcome, found a Crescent City full of kindness to those who traveled far to see and sense the Old Metropolis of the South.

"Our streets were none too clean; our hotels old fashioned and limited in number; our water supply of uninviting, muddy purity; our sewage still undisposed of in any sanitary fashion, and the vista of pleasant residences marred by unsightly cisterns, on which many households still relied for their potable and ablutionary water.

"Since 1903, yellow fever, plague and disastrous storm have visited New Orleans, and at last the fighting spirit of its people has been aroused.

"It will be a new New Orleans in 1920. To those who knew us of old, there will still be the landmarks where culinary feasts may satisfy epicurean appetites. The old French quarter still preserves its architecture and its traditions. The varying patois, argot, gombo and creole French may be heard, mingled with the Italian, which has easily been grafted in the quarter. The sightseers may still find the most of the sites of old New Orleans history, which has been much aided by the Historical Society, now exhibiting in the old Spanish Cabildo at Jackson Square.

"But leave the sentimental region and traverse the main streets of newer New Orleans and see how all has changed in these few years.

"A 'stroll on Canal Street' is a thing of the past—there is the same hurry and bustle as on State Street, or Chestnut Street, or Fifth Avenue, or Charles Street, in our Northern sister cities. Great buildings have risen, banks have stepped into the air; hotels have multiplied, streets have been paved; the sewage has been controlled; the drainage settled; and the faucet at the bath, or at the font, brings crystal water as sweet and alive as from a perpetual spring, furnished by our great Mississippi, which still rolls by and as ever fondly embraces our old and new city in its crescent fold."

Medicated Alcohol.—Pharmacists who hold a permit and have given bond are allowed to medicate alcohol and sell it for nonbeverage purposes in quantities not exceeding one pint, provided they first medicate it in accordance with any one of nine formulas specified by the commissioner of internal revenue, U. S. Treasury Department. Phenol, liquor formaldehydi and mercuric chlorid are the chief of these denaturing agents. The container of such medicated alcohol must bear a "poison" label. The sale by pharmacists of medicated alcohol for industrial purposes is prohibited. It is sold chiefly for rubbing purposes.—*Illinois Health News*, October, 1919.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ILLINOIS

Smallpox in East Moline.—The health authorities, January 12, unearthed a flagrant violation of health rules in East Moline, where six out of a family of eight were found to be suffering from smallpox without a physician in attendance.

Personal.—Dr. O. Alfred Olson, Rockford, is reported to have been arrested in a raid on communists in Rockford, January 8.—A committee of the Oak Park Physicians' Club, consisting of Drs. Arthur M. Corwin, Harry J. Stewart, Leslie W. Beebe, and Clarence E. Hemingway, January 15, cleared Dr. Thomas E. Roberts of charges that he had received remuneration for services as director of the American Red Cross Bureau in Oak Park.

Hospital Items.—Improvements costing about \$700,000 are being made at St. John's Hospital Farm, near Riverton. The next building to be erected will be for crippled children. Other structures included in the plans are a home for mentally deficient girls, a hospital for those suffering from nervous diseases and a building to be used for convalescents coming from St. John's Hospital in Springfield.—Additional buildings which have been begun at the Alton State Hospital will represent an investment of \$500,000 and will increase the capacity of the institution from 700 to 1,300.

Influenza.—Influenza is reported pandemic. The disease is of relatively mild type and few deaths are being recorded.—At the United States Naval Training Station, Great Lakes, an order was issued January 14, prohibiting gatherings in buildings and barracks, and forbidding visitors. Up to noon, January 19, 578 cases of influenza had been reported, with fifty cases of pneumonia, and three deaths.—In Chicago influenza is said to be spreading at the rate of 1,000 new cases a day. Up to January 20, 4,095 cases had been reported, with thirty-three deaths, and 891 cases of pneumonia, with 159 deaths.—Hospitals are so overcrowded that operations with the exception of emergency operations are not to be performed during this crisis.—Health Commissioner Robertson has appointed a commission of pathologists to act with the department of health in this emergency, consisting of Drs. Ludvig Hektoen, Robert Zeit, W. Henry Wilson, Arthur I. Kendall, David J. Davis, Edward O. Jordan, William A. Evans and C. St. Clair Drake.—There is a shortage of trained nurses, but the health commissioner believes that this condition will be alleviated if the recent graduates of the courses in home and public health nursing will accept positions.

Chicago

Sanitary District Health Activities.—At a meeting of the stock yards branch of the Chicago Medical Society, January 15, the activities of the sanitary district as a function in the health of Chicago were discussed by Dr. Willis O. Nance, president of the sanitary district.

China as a Field for American Activities.—The possibility of China as a field for American commerce, finance and industry were set forth in an illustrated lecture by Dr. E. H. Hume, head of the medical department of Yale-In-China, an institution maintained at Changena, at a banquet of the Yale Club of Chicago, January 10.

New Officers.—At the twenty-eighth annual meeting of the Chicago Ophthalmological Society, held in Chicago, January 19, the following officers were elected: president, Dr. Alfred N. Murray, Chicago; vice president, Dr. William R. Fringer, Rockford; secretary, Dr. Francis Lane, Chicago, and counselor, Dr. Ephraim K. Findley, Chicago.

Medical History of the War.—Three Chicago physicians are playing an important part in the preparation of the medical history of the world war. These are Drs. Casey A. Wood, Frank Billings and Harry E. Mock. The history will comprise about twenty volumes, will be encyclopedic in character, and it is promised, will be promptly issued. The first volume, which has to deal with the hospitals of the United States, was written by Dr. Wood, is now completed and is ready for press. Drs. Mock and Billings are preparing

the history of reconstruction dealing with the rehabilitation of disabled soldiers.

Hospital Asks Millions of Dollars.—At a meeting, January 17, a five-year program of expansion for the Wesley Memorial Hospital became assured. This involves the addition of \$10,000,000 worth of new buildings and the raising of an endowment fund of from \$10,000,000 to \$15,000,000. Sufficient funds have already been pledged to insure construction of the first of the four new buildings desired, which will be utilized as an addition to the nurses home. The second building will be a new section to the hospital proper which will add 1,200 beds to its capacity, a building for contagious diseases will next be erected and lastly a new power plant.

Banquet for Dr. Wood.—Dr. Casey A. Wood, the well known ophthalmologist of Chicago, has decided to retire from the practice of his specialty. The Chicago Ophthalmological Society gave a reception and banquet in honor of Dr. Wood on the occasion of its twenty-eighth annual meeting, January 19, at the Hotel LaSalle. Dr. William L. Noble presided as toastmaster, and the following responses to toasts were made: "Dr. Wood as the Ophthalmologist," by Dr. Lucien Howe, Buffalo; "Dr. Wood as Writer and Editor," by Fielding H. Garrison, Lieut.-Col., M. C., U. S. Army; "Dr. Wood as Professor of Ophthalmology," by Dr. Harold Gifford, Omaha; "Dr. Wood as Military Surgeon," by Dr. Walter P. Parker, Detroit; "Dr. Wood as Ornithologist and Comparative Anatomist," by Prof. Henry B. Ward of the University of Illinois. Brig.-Gen. H. S. Birkett, Montreal, dean of the Medical Faculty of McGill University, brought greetings from that institution. The society voted to confer honorary membership on Dr. Wood and the certificate was formally presented by Dr. Willis O. Nance. Dr. Heman H. Brown then presented Dr. Wood with a richly bound book containing the autographs of all persons present at the banquet. Dr. Wood left for his new home in Palo Alto, Calif., January 20, and expects to devote his energies to researches in comparative anatomy, working along special lines.—On January 17, the Society of Medical History was addressed by Col. Casey A. Wood on the subject "William Bailey, Author of the First Ophthalmic Treatise in English"; by Fielding H. Garrison, Lieut.-Col., M. C., U. S. Army, on "Medical Men and Music," and some remarks on the medical history of the war.

The Narcotic Problem.—At the monthly meeting of the council of the Chicago Medical Society, January 14, the committee on the narcotic problem, consisting of Drs. Joseph L. Miller, Whalen, Betz, Scelesh, Fowler and I. C. Gary, reported that the federal government, in the enactment of the Harrison Narcotic Law, had made no provision for handling the problems arising from its enforcement. Although a project is under consideration for delegating to the United States Public Health Service the institutional treatment and care of addicts, no appropriation has been made for this purpose, and therefore the state, municipality, or the physicians of the city must handle this exceedingly difficult problem. Apparently very few municipalities have made any effort to meet the situation, and in the few that have undertaken it the effort has not been rewarded by a high degree of success. Under the law only two classes of addicts may be prescribed for, excepting in the course of a bona fide reduction cure. Persons suffering from an incurable disease such as cancer or tuberculosis may be given prescriptions by the physician directly in charge, for a sufficient amount of the drug for their immediate use, and "addicts suffering from senility or the infirmities attendant upon old age" may only be given the "minimum amount of narcotic in order to sustain life." Addiction is not recognized as an incurable disease. The chief problem, therefore, is handling the addict who does not come under these two classes. The law, as construed by the supreme court, holds it a crime for any one to furnish an addict with a narcotic merely to satisfy his craving for the drug. The only circumstances in which such a person may be given a narcotic is in the course of a reduction cure, and this should be carried out in an institution. Addicts, when the drug is withdrawn, fall into the sick class and should be handled as are other indigent sick individuals. The committee had conferred with the authorities of the Cook County Hospital to determine whether or not they were willing to resume the responsibility of caring for these indigent sick. They consented to undertake the work, and will establish a dispensary at the hospital to which all patients may be referred. After the patient has been restored to apparently good health, the social service department of the hospital will attempt to secure him a position

and to exercise such friendly care as is deemed advisable. The addict, not of the first or second class, who refuses to enter a hospital would be denied a prescription as is required by law. This plan then, leaves unsolved the problem of this class of addicts. A member of the committee has conferred with the secretary of the police force, who informed him that warrants could be issued for this group of addicts on the basis of disorderly conduct or vagrancy, and they could then be confined in the Bridewell where a cure could be given, and with Judge Olson who willingly offered the cooperation of the courts in carrying out this measure. The Internal Revenue Bureau has expressed its willingness to furnish an official to supervise the work. Under this agreement the county hospital will classify and act as a clearing house for all addicts and treat those who can be induced to take the cure. The committee recommended that the council of the Chicago Medical Society accept the offer of the Cook County Hospital, that a committee of the society be appointed to assist the hospital in carrying out the measure and that the Internal Revenue Bureau, Judge Olson, the superintendent of the hospital, and chief of police each be furnished with a copy of the plan. The council, on motion, concurred in the recommendations of the committee which was continued.

INDIANA

Medical Board Officers.—The state board of medical registration and examination at its meeting, January 13, elected Dr. James M. Dinnen, Fort Wayne, president; Dr. William A. Spurgeon, Muncie, vice president; Dr. William T. Gott, Crawfordsville, secretary, and Dr. Moses S. Canfield, Frankfort, treasurer.

New Officers.—At the annual meeting of the Indianapolis Medical Society, January 6, the following officers were elected: president, Dr. James H. Taylor; vice presidents, Drs. Maxwell A. Bahr and Robert E. Repass, and secretary-treasurer, Dr. Leslie H. Maxwell. The retiring president, Dr. Charles F. Neu, in his address urged that the society open headquarters in a home of its own, and the new president said that some action will be taken this year in this regard.

Personal.—Edgar C. Loehr, Noblesville, is seriously ill at St. Vincent's Hospital.—Dr. Aldine E. Morgan, for the last three years at the head of the Indiana State Soldiers Home, Lafayette, has resigned to accept a similar position in the Marion Branch, National Soldiers Home.—Dr. George S. Bliss, superintendent of the Indiana School for Feeble-minded Youth, Fort Wayne, has resigned.—Dr. Martin L. Arthur, Patoka, has been appointed physician of Gibson County, succeeding Dr. Amos H. Rhodes, Princeton, resigned.—Dr. Hugh J. White, Hammond, has been appointed deputy coroner of Lake County.

MARYLAND

Personal.—Dr. John M. T. Finney, associate professor of surgery in the Johns Hopkins Medical School, has been invited to accept the chair of surgery at Harvard University, his alma mater, and has left for Boston to meet the directors of Harvard University.

Fund Complete.—Announcement has recently been made that the fund of \$15,000 to complete the payment on the Medical and Chirurgical Faculty building, has been raised. This fund was started last summer by Sir William Osler, who sent a check of \$1,000, expressing the hope that the sum would be raised before Christmas. The fund was completed Christmas eve.

Data Lost in Fire at the Johns Hopkins.—Valuable data and records, covering two years' research in the cause and effect of influenza, made by Dr. Thomas M. Rivers, an authority on this disease, and the laboratories of Dr. Bayne Jones and Dr. Lloyd D. Felton, containing apparatus and data of inestimable value, were destroyed in the fire which recently broke out on the top floor of the pathologic building in the Johns Hopkins Hospital group. The researches of these three physicians cannot be replaced in months.

Improvements at Johns Hopkins Hospital.—The work of repairing the pathologic building of Johns Hopkins Hospital, which was partially destroyed by fire recently, will be begun at once. Most of the damage done to the building was confined to the top floor. In addition to improving the pathologic building, the one-story structure used as a free dispensary, which has been inadequate, will be replaced by a modern structure, in keeping with the other buildings on the grounds. Plans have been prepared for the erection of a five-

story dispensary on the same site, and the building will be erected within a short time.

Report of Fort McHenry Hospital (U. S. Army General Hospital No. 2).—This army hospital reached its full maturity in 1919. From Jan. 1 to Dec. 1, 1919, there were admitted to the post, 14,277 patients, of whom 13,048 have since been discharged or removed. There were 3,285 surgical operations during the year and all but eighteen patients passed through successfully. In July there were 419 operations and no deaths, and in March, 418 operations and only one death. It has cost approximately \$3,000,000 to maintain the hospital during the year.

Psychiatric Ward at Marine Hospital.—A special ward for the treatment of patients suffering from war neuroses and mental disorders has been instituted at the Marine Hospital, Baltimore. Treatment is given to discharged members of the army, navy and marine corps under charge of the United States Public Health Service. The hospital covers District No. 4, comprising Maryland, Virginia and West Virginia. Asst. Surg. Henry E. St. Antoine has been placed in charge of the work and at present has about twenty-five patients in his care.

Dental Clinics in Schools.—Health Commissioner C. Hampson Jones has taken the first steps toward establishing municipal dental clinics in public schools in Baltimore. The work has been made possible through an appropriation of \$5,000 provided in the 1920 budget by the board of estimates. The first move will be the rehabilitation of two volunteer clinics conducted previous to January 1, by students of local dental colleges, under the supervision of Drs. B. Merrill Hopkinson and B. Holly Smith of the oral hygiene council. Five clinics, including the two already established, will probably be conducted this year, under the supervision of the health commissioner, by young dentists who may receive pay for the work. Should five clinics be established, one of them will be for colored pupils and under supervision of colored physicians.

Social Service Department at Mercy Hospital.—A new social service department was opened at the Mercy Hospital, Baltimore, January 15, under the auspices of the National Catholic War Council, whose name it will bear. This department, with headquarters at the dispensary in Mercy Hospital, will see that the poor sick of the city are given every attention, either at the hospital or in their homes. Ex-service men who are in need of medical treatment will be especially welcomed. Every day from 11 a. m. to 2 p. m. all persons suffering from the ordinary diseases will be treated; from 1 to 2 p. m. daily there will be clinics for those suffering from eye, ear, nose and throat trouble or from children's diseases. On Tuesday, Thursday and Saturday, from 1 to 2, persons suffering from skin diseases will be treated. At the same hour on Monday and Friday afternoons, orthopedic patients will be treated. The nurses in charge will not only attend to those at the dispensary but will also visit the homes of the sick. In cases where children become orphans or cannot be cared for properly by relatives, they will be given medical attention at Mercy Hospital, before being admitted to institutions. Poor persons who are bed patients at the hospital will be visited at their homes after dismissal from the hospital by nurses, who will see that they are kept in good health. Special features of the dispensary are clinical laboratories and a roentgen-ray department. All persons admitted to this department will be treated free.

MASSACHUSETTS

Flattery Medal.—A bronze bas-relief medal given by Maurice Douglas Flattery to Harvard University in 1918, has just been received by the university authorities and will be awarded later "to the person the President and Fellows of Harvard may adjudge to have made a discovery in any branch of science that would result in the greatest good to humanity in the prevention of disease or conservation of health in the broadest sense." The gift is one of a series made by Mr. Flattery, and is based on securities valued at \$7,500, the income from which is to be utilized for the annual award of a medal and \$500 in cash.

MISSISSIPPI

Hospital Opened.—A thoroughly equipped hospital has been opened at Water Valley by Drs. Leonidas S. and George A. Brown, Water Valley.

Hospital Site.—The Mississippi Methodist Conference Hospital will be located at Hattiesburg, according to a

decision of the commission which had the duty of choosing between several towns that were competing for the location of the hospital.

Personal.—Dr. M. P. Winkler, Schula, has been appointed physician for the Belmont State Farm in Holmes County.—Dr. Clyde R. Stingily has succeeded Dr. T. R. Wilson as director of the state hygienic laboratory. Dr. Stingily had previously been connected with the laboratory for twelve years.

Public Health Association Meeting.—At the annual meeting of the Public Health Association held in Jackson, Dr. William H. Frizzell, Brookhaven, was elected president, and Drs. Thomas E. Hewitt, Liberty, Amite County, Paul G. Pope, Gulfport, and F. J. Underwood, Monroe, were elected vice presidents.

Epidemic Diseases.—Dr. C. L. Williams reports that he is investigating the outbreak of dengue fever at Woodville and is satisfied that the disease was brought there by a woman visitor from Porto Rico.—Dr. W. S. Leathers has sent C. M. Ship, state investigator, to Crowder to combat a smallpox epidemic.

Hygiene Department Established.—There has recently been organized at the University of Mississippi a department of hygiene under the auspices of the Interdepartmental Social Hygiene Board, Washington, D. C., and Dr. Elise McLaurin Rutledge, Memphis, Tenn., has been placed in charge of this department.

Support Compulsory Physical Education.—Dr. J. W. Province, Clinton, president of Mississippi College; Dr. D. C. Hull, Meridian, formerly head of the Millsaps College, and Dr. Zeno Wall, Clinton, and other prominent citizens of Mississippi have accepted membership on the Mississippi Physical Examination Committee which is conducting a campaign to obtain the compulsory physical education legislation as approved by the state department of education.

New Officers.—The secretary of the Homochitto Valley Medical Society informs us of an error in the statement which appeared on page 1536 of THE JOURNAL, Nov. 15, 1919, in which Franklin County was omitted from the societies which make up the Homochitto Valley Medical Society. The vice presidents for these counties are: for Adams County, Dr. John W. D. Dicks, Natchez; for Amite County, Dr. Hiram K. Butler, Liberty; for Franklin County, Dr. Charles E. Mullens; for Jefferson County, Dr. George M. Barnes, Red Lick, and for Wilkinson County, Dr. Charles E. Catchings, Woodville. Dr. J. N. Ullman is secretary-treasurer of the society.—At the meeting of the Harrison-Stone County Medical Society at Gulfport, December 9, the following officers were elected: president, Dr. Edward C. Parker; vice presidents, Drs. Charles A. Sheeley, Gulfport, and George A. McHenry, McHenry, and secretary-treasurer, Dr. Daniel J. Williams, Gulfport.—At the meeting of the Jones County Medical Association held at the South Mississippi Charity Hospital, Ellisville, in December, Dr. Willie N. Blount was elected president; Dr. Ellison H. Williamson, Soso, vice president, and Dr. John R. Kittrell, Laurel, secretary-treasurer.—Washington County Medical Society at its meeting in Greenville, January 9, elected Dr. E. G. Martin, Benoit, president, and Dr. Woodson A. Stevens, Greenville, vice president.

MISSOURI

Smallpox in St. Joseph.—January 6, eleven cases of smallpox were reported in St. Joseph, making the total number more than fifty.

New Officers.—At the annual meeting of the Buchanan County Medical Society at St. Joseph, the following officers were elected: president, Dr. Louis G. Dandurant; vice presidents, Drs. Harry S. Conrad and Thomas M. Paul; secretary, Dr. Francis X. Hartigan, and treasurer, Dr. John M. Bell, all of St. Joseph.

Physicians' Building.—A fourteen-story building is to be erected at Eleventh and Cherry streets, Kansas City, to be used entirely by physicians and dentists. The building will cost about \$1,250,000 and the project is said to be supported by the Jackson County Medical Society and Kansas City Dental Society.

New County Hospital.—The county court has called for an election in February on a proposition to issue additional bonds to the amount of \$57,500 for the new county hospital that is to be erected in Fulton. The first bond issue of \$75,000 carried by a large majority but it was found that this was not sufficient to complete the building.

Personal.—Dr. Major G. Seelig has been appointed professor of clinical surgery in the School of Medicine of Washington University, St. Louis.—Dr. H. T. Barnes, Nelson, has been appointed superintendent of the Confederate Home, Higginsville.—Dr. Joseph J. Banskack has been appointed director of the venereal disease clinic of St. Joseph.

Influenza or Winter Cholera.—A condition which has been called winter cholera has been prevalent in children of Kansas City for more than a month. The dominant symptoms are acute indigestion, attended by nausea and diarrhea. No report has been made thus far of the seriousness of the disease. Its appearance at about the same time that influenza is prevalent in other parts of the country suggests the possibility that the condition is the intestinal form of influenza.

Health Survey and Demonstration.—The United States Public Health Service has undertaken health surveys and demonstrations in several localities of the state whereby it is hoped to establish standards for child work in the school and home. The study will be confined to those communities which afford the best prospects of putting the work on a permanent self-sustaining basis. Dr. Carlisle P. Knight, U. S. P. H. S., is in charge, assisted by Dr. Lydia A. De Vilbiss. The state board of health, American Red Cross, Missouri Tuberculosis Association, boards of education, women's organizations and city officials are cooperating in this work and the staff is made up of specialists in the different branches of medicine, nurses, field workers and clerks. The purpose is to conduct a comprehensive field investigation and demonstration in child hygiene along modern, scientific lines. In addition to this it is planned to organize a division of child hygiene within the state board of health and to assist and encourage local child hygiene activities. As a first step, agents of the Public Health Service will make a house-to-house canvass in the localities selected, and physicians and public health nurses will make visits where there are children of preschool age. Birth registration will be stimulated, prenatal supervision will be provided whenever possible or desired, and a modern health crusade will be conducted in the schools by teachers, nurses and physicians with the active cooperation of the state tuberculosis association. Schoolchildren will be examined and where necessary, suitable treatment will be recommended. Each community will be asked to make the work permanent, particularly that part of the work which provides for a full-time health officer in each community, and for the regular examination and treatment of the children.

NEW YORK

Personal.—Dr. Malcolm F. Lent, formerly medical director of Stony Wold Sanatorium, Lake Kushaqua, has been appointed supervisor of tuberculosis of the state department of health.—Dr. Herman M. Biggs, state commissioner of health, was reappointed by the governor for a term of six years, January 12, and the appointment was unanimously confirmed by the senate on the same day.—Drs. Thomas M. Holmes, Delmar, and James H. Mitchell, Jr., Cohoes, have been appointed coroner's physicians of Albany County succeeding Drs. Charles E. Bailey and James E. McDonald.

Public Water Supplies.—In an investigation made by the state department of health of the sanitary quality of the public water supply of Syracuse the question arose as to the elimination of tastes and odors due to algae growths. It has been suggested that copper sulphate be applied at the upper end of the twenty-mile conduit followed by aeration at the distributing reservoir.—Chlorination plants have recently been installed for the treatment of public water supplies at Gloversville, Gouverneur, Saratoga Springs and Sulphur Creek.—The board of water officials is considering the installation of a coagulation and sedimentation basin to be operated under pressure in connection with the pressure mechanical filters now in use at Cobleskill.

New York City

Influenza Cases Increase.—The records of the health department show that for the period from January 12 to January 16, inclusive, there were 291 new cases of influenza reported as against 97 in the preceding week.

Drug Trafficker Gets Prison Sentence.—Dr. M. A. de Preta, who was convicted of writing 50,000 prescriptions for narcotic drugs for drug addicts, was sentenced by the federal court to four years imprisonment at Atlanta. Dr. de Preta was released on \$20,000 bail pending an appeal which was entered.

New Hospital Building.—The Hospital for Deformities and Joint Diseases has purchased four parcels of real estate adjoining its present holdings. The new purchase forms a portion of the site on which a new \$1,000,000 building is to be erected for the hospital.

Personal.—Dr. Hideyo Noguchi of the Rockefeller Institute for Medical Research has gone to Progreso, Mexico, and will then proceed to Merida, to carry on confirmatory studies of *Leptospira icteroides*, and to test on a larger scale the curative properties of his specific serum.

Society of Medical Jurisprudence Opposes Health Insurance.—At the 306th regular meeting the New York Society of Medical Jurisprudence the subject of compulsory health insurance was discussed from the legal and medical standpoints by the outgoing and incoming presidents of the society. The society went on record as opposing compulsory health insurance.

Vacancies in Montefiore Staff.—The medical director of Montefiore Home and Hospital for Chronic Diseases, Gun Hill Road (East 210th Street), announces that there will be vacancies on the resident medical staff. Applications in writing may be addressed to Dr. Sigfried Wacksmann, medical director of the hospital, or applicants present themselves in person between 10 a. m. and 12 m. daily.

Great Demand for Nurses.—The annual meeting of the directors of the Henry Street Settlement was held at the Cosmopolitan Club on the evening of January 7. It was shown that the demand for nurses was constantly increasing in all boroughs, and had never been greater than at present except during the influenza epidemic. The institution has trained 176 nurses for public health service including graduate and undergraduate students.

Proper Feeding of Undernourished Children.—The Bowling Green Neighborhood Association, organized five years ago for improving health, living, and recreation conditions in the Bowling Green district, has established an experimental restaurant where it serves three meals a day to needy children to bring about the proper feeding of undernourished children. This is part of an experiment in a six months' campaign to instruct parents in the proper feeding of children.

Rockefeller Aid to Canadian Medical Schools.—In response to many inquiries regarding the distribution of a portion of John D. Rockefeller's gift to medical education, Dr. George E. Vincent, President of the Rockefeller Foundation, has issued a statement explaining that no definite policy would be adopted regarding the disbursement of the fund until after conferences were held with a large number of Canadians representing all the important institutional and geographic interests of the Dominion.

Schick Test for Children Entering School.—The health department has made arrangements whereby children entering school for the first time in February next will receive circulars relative to the value of the Schick test. Parents will be urged to have this test performed either by the family physician or by the school medical inspectors. The bureau of laboratories of the department of health is instructing the medical inspectors of the bureau of child hygiene in the technic of making these tests.

Rockefeller Foundation Buys Plot.—The Rockefeller Foundation has purchased a plot of ground, approximately 500 by 200 feet, between Sixty-Seventh and Sixty-Eighth streets, just north of the site of the hospital of the Rockefeller Institute of Medical Research. The property was formerly owned by the Presbyterian Hospital, and is assessed at \$100,000. While no definite statement has been made as to the use to which this acquisition is to be put, it is believed that it is to provide for a considerable extension of the institution's work.

Health Department Orders Study of Measles.—Because of the increase in the number of cases of measles in this city Dr. Copeland, health commissioner, has sent a letter to the division of laboratories, of which Dr. William H. Park is director, asking that a serious study of the disease be undertaken at once. During the ten days preceding January 12, 2,221 cases were reported to the health department; while at the present time from 200 to 300 cases are reported daily. Dr. Copeland states that the appearance of such a large number of cases at this time is unexpected as the disease is usually at its maximum in May.

Prohibition of Loud Noises.—At a recent meeting of the board of health a new section was added to Article 12 of the Sanitary Code which provides that automobiles and other motor vehicles equipped with gasoline or other internal combustion engine, shall be constructed so that the exhaust from

such engine is made to discharge into a muffler or other device which will prevent loud or explosive noises; and no person having the management or control of any such automobile or vehicle shall suffer or allow the exhaust from such engine to discharge into the open air, or otherwise than into a muffler or other device which would prevent loud or explosive noises.

Czecho-Slovakian Fellows of Rockefeller Foundation.—The following four physicians from Czecho-Slovakia have joined those who are now studying American methods of administration in medical schools: Drs. Zdenek Bernard, a Bohemian, 29 years of age, a graduate in 1914 of the University of Prague, who is making a special study of the organization of hygienic work in factories and the latest methods of treating venereal disease; Dr. Hynek Pelc, a graduate in 1918 of the University of Prague and later attached to the sanitary service in Cognac, France; Dr. Jaroslav Hulka, a Bohemian and graduate from the University of Prague in the class of 1919, who will devote himself to tuberculosis problems, and Dr. Karel Driml, a graduate of the University of Prague in 1914, who specializes in bacteriology and gynecology. All of these physicians have had medical experience during the war, and one was wounded in line of duty. Eight Chinese physicians, eight Chinese undergraduate medical students, four Chinese nurses, eleven medical missionaries on furlough from China, four physicians from Brazil and one physician from Salvador are also studying in America under fellowships from the Rockefeller Foundation.

PENNSYLVANIA

Philadelphia

Medical Club Meets.—The annual election and reception of the Medical Club of Philadelphia was held at the Bellevue-Stratford January 16. The officers elected were, president, Dr. Francis X. Dercum; vice presidents, Drs. Barton Cooke Hirst and Levi J. Hammond; secretary, Dr. William S. Wray, and treasurer, Dr. Lewis H. Adler.

Hospitals to Unite.—The Women's Hospital and the Women's Medical College Hospital have decided to unite. Announcement was made January 16. Committees from both hospitals had been appointed to form plans for a platform of affiliation; they will be vested with advisory powers and will arrange for a combination of dispensaries and the establishment of a purchasing department.

Personal.—Dr. Charles D. Hart has accepted the appointment as member of the board of prison inspectors for the Eastern Penitentiary.—Drs. Alice Weld Tallant and Maud Kelly who served with the French Society for Devastated France, Dr. Marianna Taylor, St. Davids, Pa., Friends Reconstruction Unit, Dr. Caroline Purnell, Commissioner to France, from the American Women's Hospitals, Dr. Regina Downe, Dr. Mary N. McLaughlan and Dr. Edith T. Morehouse of the American Women's Hospitals, Dr. Marie K. Forman of the Women's Overseas Hospital, and Dr. Laura Hunt of the Red Cross were the guests of honor at the medical college luncheon at the Adelphia January 16.

CANADA

Smallpox.—Smallpox is reported to have broken out in Winnipeg, and the medical authorities of Manitoba have placed a ban on all travelers from the south who cannot produce satisfactory certificates of vaccination.—Smallpox is reported to have broken out in twenty-six new centers throughout the province of Ontario, and the province is still virtually under quarantine.

University News.—Prof. Clarence Moore has resigned the chair of biology in Dalhousie University, Halifax, N. S., and has been succeeded by Prof. Dowell Young of Cornell University.—President, Sir Robert Falconer of the University of Toronto in his annual report, states that while the attendance has increased, the staff has decreased. The staff in 1917-1918 numbered 413, while in 1918-1919 it was 369. The total registration of students is 3,356.

Personal.—Sir Robert Borden, premier of Canada, is now on his way to Florida suffering from the effects of his exertions during the world war. He expects to be away for about six months.—Dr. John Brown, Jr., Toronto, has been made head of the physiological department of the Y. M. C. A. of North America, succeeding Dr. George J. Fisher. His title will be Senior Secretary of the Physiological Department, Home Service Committee, of the Y. M. C. A.—Major Ambrose L. Lockwood, D. S. O., M. C., Brookville, Ont., is

leaving for the Mayo Clinic, Rochester, Minn. Major Lockwood was with the Royal Army Medical Corps from 1914 to 1919.—Dr. Archibald P. Knight, emeritus professor of biology, Queen's University, Kingston, Ont., will succeed Dr. Archibald B. Macallum, retired, as representative of the department of naval service on the biologic board of the dominion government. Prof. Robert F. Ruttan, McGill University, Montreal, has also been appointed a member of the board, to fill the place vacated by Prof. John George Adami, Montreal.—Capt. Baldur H. Olson, M.D., Balfour, recently resigned as medical superintendent of the Balfour Sanatorium, B. C. He is succeeded by Dr. Francis J. Kenny.

Plans for Queen's University Medical School.—A committee of the trustees of Queen's University at a meeting held, Jan. 3, 1920, unanimously agreed on plans for the reorganization and improvement of the medical school at Kingston. A full-time dean and an adequate number of full-time clinical professors are to be secured. The university expects to obtain entire control of the Kingston General Hospital. The hospital pathologic department will be further developed; a new system of records including a complete follow-up record will be installed, and a superintendent obtained who will be responsible for the medical administration of the hospital under the supervision of the university. It is estimated that the cost of rebuilding the hospital will be approximately \$750,000, of which sum \$550,000 is already assured. The expense of securing additional full-time clinical professors and the further development of the pathologic department will be approximately \$35,000, making a total estimated expenditure of \$785,000.

Hospital News.—A new psychopathic clinic has been opened in connection with the Winnipeg General Hospital with thirty-two beds. The administration of the department will be under Dr. Alvin T. Mathers.—The municipal hospital at Fort Rouge, Man., is to be enlarged at a cost of \$1,000,000. It will be situated on the Red River, will have very extensive grounds and will be completed in 1921.—Seven new hospital districts are being established in Manitoba. They are Birtle, Deloraine, Melita, Pipestone, Souris, Erickdale and Russell. The aggregate cost will be \$200,000, authorized under the Manitoba Municipal Hospital Act.—A children's pavilion in connection with the provincial sanatorium was recently opened by Premier Martin at Fort Qu'Appelle, Sask.—The amalgamation of the Protestant General Hospital and St. Luke's Hospital, Ottawa, is said to be not far distant. Both boards have approved of the scheme. When the hospital assets are transferred to the city of Ottawa, it is hoped to have a 500 bed hospital.

GENERAL

Society Meeting.—The annual meeting of the Mid-Western Section of the American Laryngological, Rhinological and Otolological Association will be held in Colorado Springs, Colo., February 7.

Malaria.—A joint resolution authorizing the United States Public Health Service to cooperate with the states in the investigation and control of malaria and appropriating \$500,000 for this purpose was introduced in Congress, January 7, by Senator Harris of Georgia, and referred to the Public Health Committee.

Restrictions on Cuban Travel Removed.—Surgeon-General Blue, U. S. P. H. S., announced, January 6, that all restriction on travel between the United States and Cuba had been removed. Restrictions had been placed on this travel on account of the arrival to the United States from Cuba of several people suffering from smallpox.

Bacteriologists Elect Officers.—At the annual meeting of the Society of American Bacteriologists held in Boston recently, Dr. Charles Krumwiede, Bronxville, of the New York health department was elected president; Dr. F. C. Harrison, president of McDonald College, Montreal, vice president, and Dr. A. Parker Hitchens, Indianapolis, secretary (reelected).

Deaths Following Eating Ripe Olives in New York City.—During the past week newspapers recorded the deaths of six persons in New York City from eating olives. The brand of olives at fault has not yet been stated nor are the details available. It is stated, however, that the deaths were probably due to poisoning with toxins of *Bacillus botulinus*, similar to deaths occurring in Canton, Ohio, and in Detroit, also following eating ripe olives.

Porto Rico Physicians Hold Meeting.—At the annual meeting of the Porto Rico Medical Association held in San

Juan, December 19, 20 and 21, under the presidency of Dr. Jorge del Toro, the following officers were elected: president, Dr. Pedro Malaret, Ponce; vice president, Dr. Pedro Del Valle Atilas, San Juan; secretary, Dr. Agustín A. Langier, San Juan; treasurer, Dr. Jacinto Aviles Borrero, San Juan, and counselor, Dr. Rafael Lopez Sicardo, San Juan. It was decided that the next meeting of the Association be held at Ponce, Dec. 11 and 12, 1920.

Uniformity of Labeling.—The Committee on Agriculture of the United States Senate recently held hearings on the bill of Senator Calder of New York to bring about uniformity in labeling of food and drug products in interstate commerce. The bill was designed to eliminate the conflicting regulations made by the various states. In view of the fact that the Department of Agriculture has interposed objections to its practicability and has presented an opinion seriously questioning the constitutionality of the bill, it is probable that the bill will not receive the approval of the committee.

Mental Hygienists to Meet.—The third annual convention of the Mental Hygiene Society of the United States and Canada will be held in New York City, February 4-5, under the auspices of the National Committee for Mental Hygiene and the Committee on Mental Hygiene of the New York State Charities Aid Association. The mental hygiene lessons of the war are to be one of the chief subjects of consideration at the meeting, at which Major-Gen. Merritte W. Ireland, Surgeon-General, U. S. Army, will preside. Dr. Pearce Bailey will describe the examinations which were used to determine in advance whether or not the soldiers would bear the strain of war, and Dr. Thomas W. Salmon, medical director of the National Committee for Mental Hygiene, will describe methods whereby the procedures employed in dealing with mental and nervous diseases in the American Expeditionary Forces may be applied in civil life. At this meeting twenty-two states and Canada will be represented.

Association for the Advancement of Science.—The seventy-second meeting of the American Association for the Advancement of Science and the affiliated national scientific societies was held in St. Louis, December 29 to January 3, under the presidency of Dr. Simon Flexner, New York. A change in the constitution was made which changed the title of Section H from anthropology and archeology to anthropology and that of Section I from psychology and philosophy to psychology. On the evening of January 1, the presidential address on "Present Problems in Medical Research" was delivered. Among the officers elected were: Dr. L. O. Howard, Bureau of Entomology, Washington, president; Prof. E. L. Nichols, Cornell University, Ithaca, N. Y., general secretary; E. K. Strong, Jr., Carnegie Institute of Technology, Pittsburgh, vice president, Section I, psychology, and Dr. Joseph Erlanger, Washington University, St. Louis, vice president, Section N, medicine.

Bequests and Donations.—The following bequests and donations have recently been announced:

Home of the Merciful Saviour for Crippled Children, Rush Hospital for Consumptives, Children's Seashore Home, Chelsea, N. J., and Children's County Week Association, Philadelphia, each \$1,000 and the residue of the estate after a few private bequests to the Episcopal Hospital, Philadelphia, for the maintenance of two free beds.

King's Daughters Memorial Hospital, Greenville, Miss., a donation of \$5,000 from the Goyer Company, Memphis, Tenn., for the hospital building fund.

St. Peter's Hospital, Charlotte, N. C., a donation of \$10,000 in memory of his grandson, Hamilton C. Jones, III, by W. A. Irwin, Durham. The donation is to be used to build an annex to the hospital, including a children's ward and maternity ward.

Grant Hospital, Chicago, \$100,000; Alexian Brothers' and Michael Reese Hospitals, Chicago, each \$5,000; United Charities of Chicago, \$5,000, by the will of Mrs. Catherine Seipp.

Children's Memorial Hospital, Chicago, \$10,000, the earnings of the Rummage Shop for the endowment of a bed in the hospital in memory of Dr. Walter Shield Christopher.

Bills in Congress.—Representative Henry T. Rainey has introduced in the House of Representatives a bill to provide for the care and treatment of drug addicts identical to that introduced in the Senate by Senator France of Maryland, Chairman of the Committee on Public Health and National Quarantine.—The Public Health Service is supporting a bill introduced by Hon. James E. Reed of Missouri for the purchase of a site and erection of a new hospital in St. Louis, to take the place of the old Marine Hospital which has been conducted under the auspices of the Public Health Service. An appropriation of \$1,600,000 is requested, and it is reported that the donation of a considerable amount of land will be made to the Government by St. Louis interests in the event that the bill is passed.—The Public Health

Service is also interested in the purchase of the West Baden Hotel at West Baden, Ind., to be operated as a government hospital.—Senator Kenyon of Iowa has favorably reported the bill heretofore passed by the House of Representatives, "for the promotion of vocational rehabilitation of persons disabled in industry." The purpose of this legislation is to enable civilians who have been permanently disabled or injured in industrial pursuits, to learn trades in order to carry on gainful occupations. The measure is similar in character to that providing for soldiers who have been injured in the war. The bill provides for cooperation with the various states and requires that each state shall expend in the work the same amount as that expended by the federal government within that state.—A bill has been introduced by Representative J. S. Webster of Washington which will permit any Surgeon, Assistant Surgeon, or other medical officer of the Public Health Service who resigned for the purpose of entering the army or navy to be restored to his former position in the Public Health Service.

FOREIGN

Work of Zionist Unit.—The report of the American Zionist Medical Unit, a body of about fifty physicians and nurses which began to function in Palestine in 1918, under the leadership of Dr. Isaac M. Rubinow, New York shows that it has established three hospitals, six dispensaries, three bacteriologic laboratories, two training schools for nurses and has organized sanitary squads in Jerusalem, Jaffa, Haifa, Tiberias, and Safed. The unit has also inaugurated a campaign against the mosquito and malaria, and in four weeks the mosquito-infected cisterns of Safed were reduced from 35 per cent. to 5 per cent.

Stammering Children.—There are about 1,200 stammering children attending elementary schools in London. The London County Council, realizing that such children are handicapped in getting employment, is about to organize special classes for them before they leave school. The classes will be started in different parts of London, and teachers, specially qualified for dealing with speech defects, will be appointed. The traveling expenses of children attending the classes will be paid by the council. The children will receive about twenty lessons in speech training.

Help for Foreign Physicians in Need.—The *Ugeskrift for Læger*, Copenhagen, relates: "Committees have been organized in Denmark, Norway and Sweden to aid those suffering most from the war. The aim is to help where the need is greatest, namely, in Austria, in the Baltic countries and in Belgium, and also in Poland and in Germany. It is planned for colleagues to help colleagues or their families, that is, for physicians to help physicians, clergymen to help clergymen, and so on. The plan is to send parcels or money, a package of food, clothing, soap, etc., every week or second week until the end of March, or to offer to take children into one's home. The central committee supplies the addresses of those who have applied for aid, and the aid is extended through the committees or the Red Cross. By this arrangement it is insured that the parcels, etc., will reach the addressees and that there will not be duplication of efforts."

LATIN AMERICA

Organization of the Mexican Medical Association.—Dr. Rosendo Amor E., acting dean of the school of medicine of the National University of Mexico, has been making a trip through various states, organizing branches of the Mexican Medical Association. Branches have already been established at Querétaro, Celaya, Guanajuato, León and Aguascalientes. The officers of the Aguascalientes Society are the following: president, Dr. Francisco C. Macías; secretary, Dr. Manuel I. Rodríguez, and treasurer, Dr. Alfonso M. López.

The Medical Profession in Colombia.—In an editorial in the November issue of the *Repertorio de Medicina y Cirugía*, Bogotá, Colombia, attention is invited to the possible effect on the medical profession of that country, of the new conditions in other countries created by the war. Our contemporary is apparently in fear that the young physicians graduating by the thousand from European and American universities may go to Colombia "in search of peace, freedom and money." The *Repertorio* is especially alarmed at the migration from the United States which it terms picturesquely "the land of the voracious eagle, the stars and stripes" and lays stress on the presence of some American physicians in various Colombian cities and the number of patients who go to Panama to be treated by American physicians.

Government Services

Personnel of the Medical Department

For the week ending Jan. 16, 1920, the medical department of the Army contained 2,117 medical officers, including 1 major-general, 2 brigadier-generals, 167 colonels, 159 lieutenant-colonels, 515 majors, 798 captains and 475 lieutenants. The Medical Reserve Corps contained 4,413 officers, an increase of 65 over the previous week. These were distributed as 2 brigadier-generals, 74 colonels, 276 lieutenant-colonels, 1,257 majors, 1,829 captains and 975 lieutenants. The records of the general staff show 7,539 medical reserve officers as of Jan. 16, 1920. It is explained that these figures are not an absolutely accurate statement of the Reserve Corps as they include about 1,500 of the latest recommendations from which declinations have not been deducted, and do not include a number of recommendations which have been forwarded from the Surgeon-General's Office to the Adjutant-General's Office but which have not yet been acted on in the latter office.

Award of Prizes by the Academy of Medicine

The Academy of Medicine held its annual meeting, December 16, at which the secretary, Professor Achard, read the names of those to whom the academy had awarded prizes for the year 1919.

The Adrien Buisson prize of 10,500 francs, which is given every three years to the originator of the best method of treating recognized diseases that in the present stage of medical science are regarded as incurable, was bestowed on Dr. Saquépée, agrégé professor at the Ecole d'application de médecine et de pharmacie militaires du Val-de-Grâce, and on Dr. de la Vergne, of the government military bacteriologic laboratory at Strasbourg.

The Théodore Herpin prize of 3,000 francs is given to the author of the best work on epilepsy and nervous diseases, and was bestowed on Dr. Fernand Netter of Paris.

The Henri Huchard prize of 6,300 francs was awarded to Dr. Clair of Paris for having eminently distinguished himself during the war of 1914-1918 by the care he gave to the sick and wounded.

The Berraute prize (a 3,092 franc 3 per cent bond) was bestowed on Dr. Paine, director of the institute for cancer research in Brompton, and on Dr. Albert Peyron, head of the military laboratory for cancer research in the Hôtel-Dieu, Paris.

The François-Joseph Audiffred prize (a 24,000 franc 3 per cent. bond) is to be given to the person, without provisions as to nationality or profession, who within a time limit of twenty-five years beginning with April 2, 1896, shall have discovered a curative or preventive remedy which shall be recognized by the Academy of Medicine as efficacious or sovereign in the treatment of tuberculosis. This prize was not awarded.

Death of Troisier

Dr. E. Troisier, physician of the Hôpitaux de Paris and agrégé professor of the Paris Faculty of Medicine, died

recently, after a short illness, at the age of 75. Troisier, who was born at Savigny, department of the Ardennes, April 6, 1844, was descended from a family of physicians. His classical study was done in the *lycée* at Reims. Later he came to Paris to study medicine. He was appointed hospital physician in Paris in 1879. He became agrégé professor the following year, at the same time as Joffroy, Landouzy and Raymond. In 1901 he was elected a member of the Academy of Medicine in the section of medical pathology, and for a time was the secretary of the academy. Troisier published a large number of works, some of which have remained classic. His researches on supraclavicular adenopathy in abdominal cancer (1886-1889) have proved to be of great value, and the enlarged supraclavicular gland that sometimes is seen in cancer of the stomach or of the intestine is named the Troisier ganglion after him. He also published researches on pulmonary lymphangitis (1874), cancerous lymphangitis (1874-1901), cancer of the thoracic duct (1897), metapneumonic pleurisy, and other conditions.

Medical Men in Chamber of Deputies

From the standpoint of industries and professions represented, the newly elected chamber of deputies presents quite a different aspect from the chamber of 1914. The number of industrialists has almost doubled (fifty in place of twenty-six). The agriculturists are represented by fifty-two instead of nineteen. The legal profession, however, still has a large majority: 140, as compared with 148 who had seats in the chamber of 1914. The representatives of the medical profession have decreased. In 1914 they came right after the lawyers in the point of numbers, holding, as they did, fifty-four seats, whereas the new chamber has only forty-one, with the result that they are exceeded by the capitalists, the industrialists and the agriculturists.

A Welfare Society of the Foreign Colonies in France

The Union des Colonies étrangères en France, founded for the purpose of rendering aid to the victims of the war, has just held its fourth general meeting, under the presidency of Walter Berry. Mrs. Edmund L. Baylies, president of the American Committee of New York, was also present. Since the war the union has founded and supported five schools in which crippled and disabled soldiers are trained for some trade or profession, among which schools was that of Maison-Blanche in Neuilly-sur-Marne (*THE JOURNAL*, Jan. 17, 1920, p. 190). The union has collected in gifts and assessments nearly 5,000,000 francs, and has given training to 7,000 men.

The Effects of High Altitudes

At the last meeting of the Academy of Sciences, Dr. Raoul Bayeux submitted an interesting communication in regard to scientific observations that he made during an ascent of Mont Blanc. According to Bayeux, the discomforts of high altitudes are caused by urinary intoxication. A large number of urinalyses made between Chamonix, the village at the foot of Mont Blanc, and Mont Blanc Observatory have shown that the toxicity of the urine increases rapidly among the inhabitants as the higher altitudes are reached. This toxicity is, however, notably decreased if oxygen is injected subcutaneously. Owing to such injections, Bayeux was able to spend eleven days on Mont Blanc at an altitude of 4,400 meters without suffering any ill effects.

Roentgenographic Examination of the Abdominal Viscera

At a recent meeting of the Société médicale des hôpitaux de Paris, Dr. Ribadeau-Dumas exhibited a number of roentgenograms of the abdominal organs (liver, spleen, kidneys, gall-bladder) that were taken after the intra-abdominal injection of oxygen (induced pneumoperitoneum). Remarkably clear plates are thus secured. These injections were found to be harmless and caused no discomfort. Dr. R. Bensaude stated that he preferred to inject simply air with a syringe, and that a high degree of visibility of the abdominal organs is thereby secured. After the roentgenographic examination is over, all that is necessary to do in order to draw out the air is to press on the patient's abdomen. Bensaude has never seen any ill effects from these injections, unless it be an occasional slight painful sensation in the dorsolumbar region.

Diabetes and Exophthalmic Goiter

Dr. Marcel Labbé reported to the Société médicale des hôpitaux de Paris five cases of diabetes associated with exophthalmic goiter. All the different forms of diabetes were to be found associated with the exophthalmic goiter: simple alimentary-glycosuria, diabetes without denutrition, diabetes with denutrition, and diabetes accompanied by acidosis,

resulting in death during coma. But this diabetes has certain special features. The glycosuria seems to be less affected by diet than usual. The evolutionary stages of the disease coincide with those of the exophthalmic goiter. At times, crises in the exophthalmic goiter occur, accompanied by extreme tachycardia, pulsations of the goiter, and diarrhea, together with severe polyuria, an increase of the glycosuria, considerable azoturia (from 44 to 48 gm.) and acidosis. Moreover, it was found that acidosis is a very common complication in the diabetes of exophthalmic goiter patients. According to Labbé, the medicaments that act on the goiter act also on the diabetes. Iodin has been found particularly efficacious in treating the two syndromes. Dr. Sicard, however, opposes this view and thinks that iodine aggravates the symptoms of exophthalmic goiter.

LONDON

JAN. 3, 1920.

Sir William Osler

The death of Sir William Osler has cast a gloom over the whole profession. In spite of his years, his activities were so great and his outlook so fresh that we never regarded him as an old man. Great physician, great teacher, great scholar, great writer is how one would sum him up. To certain others, even in his own time, some of these terms can be applied with equal force; but to whom can they all be applied? The name of his great compeer of Cambridge comes to the lips, and we know enough to say (*THE JOURNAL*, Aug. 30, 1919, p. 706) that the comparison would not have been unwelcome to Osler. Though alike in all these qualities, Sir William Osler and Sir Clifford Allbutt differed much and in a way not easy to define. Osler's career was, of course, widely different, and he stood alone in his remarkable influence on medicine in two continents. He seemed to be medicine personified. He combined the backward glance at the achievements of the past with the forward glance of the latest investigations in a fuller measure than any other man excepting the venerable one referred to, with whom comparison seems unavoidable. Above all, there was his winning personality, his single-minded enthusiasm for knowledge, his kindness to his fellow man, whether colleague, student or patient. No wonder, to use his own words, the benediction of friendship followed him like a shadow, and he had the sense of comradeship in work without the petty pinpricks of jealousies and controversies.

As all who read these lines are doubtless familiar with his earlier American career, I will begin with his arrival in England. His reason for leaving Baltimore he gave as follows (*Brit. M. J.*, Jan. 3, 1914): "I had had thirty-one years of uninterrupted hard work. William Pepper, my predecessor in Philadelphia, died of angina at 55. John Musser, my successor, died of the same disease at 53. I had had a good inning, and was glad to get away without a serious breakdown." The intellectual calm of Oxford, where he had ample leisure for his literary and educational work, was a welcome relief after his American life, which had become too strenuous. When in 1905 he succeeded Sir John Burdon Sanderson in the Regius Professorship of Medicine, he brought to a somewhat antiquated school an unrivaled experience of the most modern schools and an enthusiasm for reform. It was, indeed, an ideal appointment. He was then 55 and at the height of his fame. The school was small and in some ways cut off from the other activities of the university. He soon wrought a change. His breadth of learning and manifold activities provided links with other departments. He brought the academic teaching of medicine more fully into touch with practice. He helped to develop the departments of pathology and physiology. At the Radcliffe infirmary he greatly improved the clinical teaching, and combined practice with scientific research and academic exposition as had never been done before. Mainly through his efforts a new clinical laboratory was built. For his antiquarian interests and delight in books, Oxford provided an ideal home. He spent much of his leisure in the famous Bodleian library, of which he was a curator. Of the happiness of his life at Oxford he has often borne testimony. Then came the war and the great blow of the loss of his only son in the field. He bore up bravely and continued his work, immersing himself in all the additional duties which war hospitals provided. But the loss told heavily on him and it has been described as a mortal wound. His presidency of the Fellowship of Medicine was inevitable, for no man was more devoted to the ideal of linking up the English-speaking races or had done so much for it. The open hospitality of his house at Oxford to Americans and other travelers, and his helpfulness

to them will long be cherished as a memory by many. He was always responsive to the appeals of friends abroad, was anxious about wounded sons, and undertook long and fatiguing journeys. While called in consultation in Glasgow he was caught by the railway strike, and undertook a long motor drive from Newcastle to Oxford. He arrived ill. For three months he suffered from bronchitis and pneumonia of an ill-defined type. An operation for empyema became necessary just before Christmas and seemed to promise favorably, but he died suddenly, Dec. 29, in his seventy-first year. A large and representative gathering attended the funeral service, which took place at Christ Church Cathedral, Oxford. Among the chief mourners were Lady Osler, Dr. W. Francis, Mrs. Henry Chapin, Sir Archibald Mellock, Miss Emmons and Mr. and Mrs. Frank Osler. In the congregation were the vice chancellor; the senior and junior proctors; Sir Frederick Treves; Prof. G. H. F. Nuttall; Prof. Sir T. Clifford Allbutt; Sir Norman Moore, representing the Royal College of Physicians; Sir H. D. Rolleston, representing the Royal Society of Medicine; Colonel Harvey, representing the director-general of the army medical service; Sir George Perley, representing the high commissioner for Canada; Dr. W. Collier, representing the British Medical Association; Dr. E. J. Woods, representing the Association of American Physicians; Mr. E. Maclean, representing the American University Union in Europe; Lieut.-Col. G. W. Badgeron, representing the Academy of Medicine and the University of Toronto, and Col. J. G. Adami, chancellor of the University of Liverpool. The body was taken to London for cremation.

Panel Physicians Demand Increased Remuneration

The great increase in the cost of living—amounting to more than 100 per cent.—has led to an increase of physicians' fees. Recently the British Medical Association decided that medical fees should be increased by 50 per cent. The turn has now come of panel physicians who work under a fixed capitation fee of about \$1.50 per insured person. The Insurance Acts Committee of the British Medical Association has decided that under present circumstances \$3 is the lowest capitation fee that can properly be accepted for an effective service. A conference on the subject has been held between representatives of the association and Dr. Addison, minister of health. Sir Clifford Allbutt, president of the association, stated that the parallel to the present insurance practice was the club practice, in which the average capitation fee was \$1. In some cases the service was poor, but in others expensive drugs were used and the service on the whole was not unsatisfactory. The club physician, however, did not entirely depend on his clubs for a living, and not infrequently this part of his work resulted in a loss. With the passing of the insurance act the capitation fee had to be regarded in the majority of cases as a sum which would provide reasonable remuneration for a physician whose insurance patients occupied the greater part of his time. They had now to consider: (1) the fall in the value of money, and (2) the increased demand on the physician and the improved standard of work. In his experience in consulting practice, a patient required an hour's time for work for which twenty years ago a quarter of an hour would have been ample. He also referred to the increased cost of medical training, and emphasized the need of a good standard of remuneration in order to attract young men of the best type.

In replying, the minister of health recognized that there were increasing demands for an improved standard of service and that an impetus had been given to these demands by the illustration afforded by the war of what could be done by medical science. As a remuneration, there was no possibility of hoping to satisfy extremists, but he would do his best for the fair-minded man with a proper professional standard. Whatever might be the ideal arrangement, regard must be had to the state of the public finances. He did not think that the case for a \$3 capitation fee had been made out. A distinction must be drawn between the percentage increase of the wages of the laboring classes (which must almost inevitably go in actual expenditure on food) and the case, for example, of men in the civil service receiving an income more or less comparable with that of an average physician. There was a case for a substantial increase over the prewar fee, and the new fee must be one which would give a good average physician, fairly doing his duty, what he himself would feel would pay him.

Close of the Belgian Physicians' and Pharmacists' Relief Fund

A meeting of the constituents of this fund was addressed by Dr. V. Pechère, president of the Belgian National Relief Committee for Physicians and Pharmacists, which during the

war distributed at Brussels the money received from the British and other funds. He told how during the war the Belgian committee many times tried to send to England its regular reports but were prevented by the Germans. At the end of August, 1914, when it heard of the destruction and the atrocities committed in eastern Belgium by the Germans, the committee tried to establish a committee to succor their *confrères sinistrés*. But it was difficult to get any exact information as to what had happened, because of the German regulations, which rendered traveling almost impossible. There was no postal service, much less telegraph or telephone. It was the beginning of the prison régime. The committee got by subscription in Belgium 180,000 francs, from foreign lands 100,000 francs, and from England \$135,000. With this sum it was able to save 140 families, more than 400 persons. One of the reasons for help was the disappearance of the head of the family.

Operation Amid Flames

The king has decorated with the Albert medal Capt. Charles Hoskyn. On the occasion of a railway accident in France, a man was pinned down by the leg under heavy girders. The wreckage was on fire and the flames had reached his ankles. Captain Hoskyn crawled into a cavity in the flaming wreckage, released one of the man's legs, amputated the other, and assisted in bringing the poor fellow out alive, retaining hold of the main artery until a tourniquet could be applied.

The Cost of Tuberculosis

The annual report of the Local Government Board, just issued, deals fully with the work carried out on tuberculosis. The number of beds provided by local authorities in sanatoriums and hospitals has increased from 1,500 in 1911 to 7,038. The number of dispensaries provided has increased from thirty to 349. In addition, four large sanatoriums, containing in all 650 beds, will soon be available. The gross expenditure by local authorities on the treatment of tuberculosis from July 15, 1912, to March 31, 1919, is estimated to have exceeded \$25,000,000. Efforts have been made to handle the cases of the tuberculous ex-soldier and sailor and the organization is on a better footing than while the war lasted. In addition, the board has approved of four training colonies where consumptives can be taught suitable occupations.

GUAYAQUIL

Dec 10, 1919.

Leishmaniosis in Ecuador

Dr. Alfredo J. Valenzuela V., professor of internal pathology at the University of Guayas, presented before the physicians and medical students of this city two cases of leishmaniosis confirmed bacteriologically by Dr. José D. Moral. The cases were very interesting because of their having been confirmed microscopically and having responded to the specific treatment.

Sanitary Conditions

For the last six months there has not been a case of yellow fever. Dr. M. E. Connor of the Rockefeller Foundation is continuing his campaign against the mosquitoes that carry yellow fever.

Dr. León Becerra, director of sanitation, in association with Dr. Connor has just begun a campaign against hookworm disease, which is prevalent in this country.

Personal

After having accompanied General Gorgas and Colonel Lyster on their trip in Central America to study yellow fever conditions, Dr. W. Pareja, one of the quarantine physicians of this port, who also belongs to the Rockefeller Foundation, has returned to this city.

VIENNA

Dec. 18, 1919.

Effects of the War on General Health in Vienna

The five years of war, together with the deplorable tragedy of the few months of so-called peace, have had a most detrimental effect on the general condition of the population of this city. More than 2,000,000 people, over 30 per cent. of the entire population of this new state, are dependent on outside supplies of food and fuel, which in peace times were furnished in abundance, but now are lacking every day more and more. The striking feature in the life of the city is the scarcity, or rather absence, of young children on the streets. The birth rate from 1918 to 1919 was less than 30 per cent. of the figure for 1914. Another, most visible, feature is the leanness

of the people. Formerly, a certain stoutness of the middle-aged persons, especially the women, was noticeable. The vast majority of the population have lost over 15 per cent. of their weight, many even much more. This is due to the hardly credible reduction in the supply of food, with which the Viennese have to cope. The qualitative and quantitative food values are so low that the calculated minimum of calories of 2,300 a day is never reached by the ration allowed by the government to each inhabitant. Lately this figure fell to 1,270. The effect is the visible undernutrition of the population, especially of children and the aged. The official report of the board of health of Vienna states that in 1914 the mortality rate was 16.25 per thousand of population (33,258 deaths). In 1918 it was over 26 per thousand (52,492 deaths). In 1914, tuberculosis was responsible for 6,223 deaths; in 1918, the figure went up to 11,531. So far in 1919, more than 12,000 persons have died from this disease. Thus, aside from emigration, which has assumed such proportions that one can speak with truth of the flight from Vienna (everybody in a position to do so has moved elsewhere), the population is constantly decreasing because of natural causes. The last few years have furnished an experiment on a large scale as to the lowest amount of food with which life can be continued. It has been proved that 3,000 calories, the figures given heretofore, are incorrect. They are much too high, for the amount of food consumed by the general population here, though far below that margin, has kept us alive and fit for work to a moderate degree, at least.

The condition of the new-born and of children up to 4 years has been studied by Dr. T. Weiss, who has found that 90 per cent. of all children born in the last three years show more or less marked signs of rickets; especially is this true of those born after 1917. The weight of all young babes was from 15 to 20 per cent. under normal. The older children were up to 33 per cent. under normal, so that a 4 year old child looked like a 2 year old. Even the children 9 or 10 years of age look as if they were only 6 or 7. These figures pertain to the poorer and middle classes. Among the rich, children show a little more favorable condition, but there, too, the quality of the food has not been satisfactory, in spite of wealth, for good food was and is not as yet obtainable at any price. Even children of the wealthy are rickety, anemic and weakly, although in better shape than the children of the poorer classes.

The inadequate nutrition of adults could also be easily recognized in a large number of cases by signs of bone diseases rarely encountered in normal times. Thus osteomalacia was frequently seen in the hospitals, not only in females, but also in males. Cases of obstinate "rheumatism," of "back-ache," of "colds" were disclosed by exact investigation to be due to softening of bones, produced by lack of calcium in the system. The diet often was entirely lacking in fat, and consisted principally of vegetarian products—cabbage, beets, and similar vegetables, not used as an exclusive diet except in times of stress. Furthermore, so-called "hunger edema" has been often noted in hospitals. Patients came with general anasarca, which, however, soon disappeared on administration of food containing vitamins. A marked decrease of diseases of the digestive organs has been evident, especially as regards the inflammatory and catarrhal type; also gout and diabetes have been less frequent. Dermatoses and furunculosis have been very annoying lately; especially scabies has become a real scourge. Arrangements have been made in our general hospitals for antiscabies treatment on a large scale. Wilkinson's compound sulphur ointment is the universally adopted remedy, followed by a zinc application. The body of the patient is well rubbed with this ointment. He is then given a soap bath, which treatment is repeated three times within two hours. Meanwhile the linen and the clothing of the patient are disinfected by a vapor process. By means of this rapid cure, hundreds of cases are dealt with daily.

A frequent figure in hospitals as well as in the practitioner's office is the war invalid. The total figure for the crippled and disabled soldiers of the former Austro-Hungarian army is placed at 380,000, which includes the blind, the deaf, the diseased and the mutilated. Of this total, about 120,000 fell to the lot of the present Austrian Republic. Needless to say, the majority of these men are in the capital and demand the more or less constant care of skilled medical men. They take up a large percentage of the hospital beds. Therefore, an invalids hospital has been established, and the former military hospitals have been turned over to a committee for the care of war cripples and invalids. A special orthopedic hospital under Professor Spitzky is in full working order in Vienna, and is supplied with all the most up-to-date appliances for the care of the armless or otherwise crippled per-

sons. A visit to Vienna just now would be worth while for the American physician. Aside from the food problem, which the American Mission or the American embassy here would no doubt help citizens of the United States to solve, life would be very cheap here, as one dollar is now equivalent to nearly 200 kronen, or forty times its peace value. The prevailing prices, however, are only twenty times those of peace times. There is a good deal of medical work to be seen and much to be learned here at present along the line of special plastic surgery, pediatrics, chemistry and general pathology. Details will be given in a following letter.

The conditions affecting the general practitioner are now undergoing a transformation. Owing to ideas creeping in from Russia and Hungary, where socialistic methods and institutions have to a large degree interfered with the physician and his work, certain changes seem inevitable. Thus, the socialization, that is, the absolute control by the state of the physician and his time, place and method of work, was at one time contemplated by our government. Only the unanimous opposition of the profession, which an almost universal organization made possible, has averted the danger thus far. But a strict and continuous watch over affairs is necessary.

BUENOS AIRES

DEC. 6, 1919.

New Plan for Medical Teaching

One of the changes made by the new national plan of studies in the laws relating to universities prescribes that no profession shall require more than six years of study. Though there was some doubt as to the legality of this provision since the right to legislate on these subjects belongs to Congress, this measure has been accepted. The board of directors of the school of medicine has just approved a plan of reforms according to which the study of medicine will take only six years. The plan to distribute the studies in five periods was rejected, the distribution in years being approved instead, with compulsory examinations. Several specialties will be studied now in a semester (really four months) instead of a year. In view of local habits the plan has not been received with much enthusiasm by the students who favor the seven years period heretofore in force. The age of retirement for professors has been fixed at 65 years. There has been proposed the establishment of several new chairs: infant surgery and orthopedics, and the branching off of pharmacodynamics and therapeutics.

Influenza in Young Children

The Society of Pediatrics has held a sort of miniature congress devoted to the study of the latest epidemic of influenza among infants. The various speakers called attention to the fact that the disease attacks also little children (Dr. Elizalde), and that the influenzal bronchopneumonias are less serious than those due to measles or whooping cough (Dr. Centeno). There have been observed some cases of military bronchopneumonia that simulated military tuberculosis (Dr. Bacigalupo). All agreed as to the worthlessness of the pneumococcic vaccine called haptinogeno neummo of Dr. Méndez.

The Rockefeller Foundation Commission

The University of Tucuman has asked—and its request has been successful—that the Rockefeller Foundation Commission send a medical commission to study malaria and its prophylaxis in the province of Tucuman.

Marriages

LUCIUS WILLIAM CASE, Pomona, Calif., to Miss Jennie M. Flanner of Jackson, Mich., at Pomona, January 1.

WILLIAM HENRY MACKEY, Philadelphia, to Miss Florence M. Gompers of Washington, D. C., December 25.

MALFORD WILCOX THIELIS, Wakefield, R. I., to Miss Christiane Cherfils of Paris, France, December 10.

ROSWELL TALMADGE PETTIT, Ottawa, Ill., to Miss Dorothy Blatchford of Oak Park, Ill., January 16.

HENRY JACKSON, JR., Baltimore, to Miss Isabella Dove Lee of Chestnut Hill, Boston, January 3.

HAROLD FREDERICK LANSHE to Miss Elizabeth B. Taylor, both of Allentown, Pa., recently.

HARRY S. BERMAN, Detroit, to Miss Caroline Block of Gordonsville, Va., December 23.

Deaths

William Samuel Gottheil * New York City; College of Physicians and Surgeons in the City of New York, 1882; aged 60; a specialist in dermatology; professor of dermatology in the New York School of Clinical Medicine; a fellow of the New York Academy of Medicine; a member of the American Dermatological Society; dermatologist to the City and Lebanon hospitals, New York City; consulting dermatologist to Beth Israel, Washington Heights, Jewish Maternity, and Rockaway Beach hospitals, and the Hospital for Deformities and Joint Diseases, New York City; died January 7, from heart disease.

Wallace Edgar Sabin * Lieut., M. C., U. S. Army (retired), Anna, Ill.; College of Physicians and Surgeons in the City of New York, 1868; aged 74; contract surgeon, U. S. Army from December, 1869, until September, 1892, and from 1898 to 1908; commissioned first lieutenant, Medical Reserve Corps, July 7, 1908, and first lieutenant, Medical Corps, May 22, 1909, and retired by operation of law, June 7, 1909; a member of the Association of Military Surgeons of the United States; died at the home of his brother, January 10, from angina pectoris.

Charles Philip Pinckard, Chicago; Harvard University Medical School, 1889; aged 55; a member of the Illinois State Medical Society; a specialist in diseases of the eye; and one of the founders of the Chicago Ophthalmological Society; attending ophthalmologist to Michael Reese Hospital and the dispensary of that institution, and to the Home for Crippled Children; died January 17, from heart disease.

Hilary M. Christian * Philadelphia; University of Pennsylvania, Philadelphia, 1882; aged 61; professor of genito-urinary diseases in his alma mater; a member of the genito-urinary staff of the German Hospital; formerly clinical professor of surgery in the Medico-Chirurgical College of Philadelphia; died in the Presbyterian Hospital, Philadelphia, January 7.

Emma Valeria Pintard Bicknell Culbertson * Boston; Woman's Medical College of Pennsylvania, Philadelphia, 1881; aged 65; a member of the American Academy of Medicine; a specialist in surgery and gynecology; attending surgeon to the New England Hospital for Women and Children, Boston, since 1883; died in St. Petersburg, Fla., January 9.

Richard Justus Swoboda * Philadelphia; Medico-Chirurgical College of Philadelphia, 1906; aged 36; associate professor of chemistry and toxicology in Temple University, Philadelphia; for nine years a district physician under the department of health and charities; died January 3, from a nervous breakdown.

Byron H. Phelps, Corry, Pa.; Western Reserve University, Cleveland, 1871; aged 75; consulting surgeon to the Corry Hospital; formerly mayor of Corry and president of the local board of health; while crossing the railway tracks at Spartansburg, Pa., January 5, was struck by a train and instantly killed.

Britton Duroc Evans * Greystone Park, N. J.; College of Physicians and Surgeons, Baltimore, 1885; aged 61; medical director of the New Jersey State Hospital, Morris Plains; a medicolegal expert in insanity and mental diseases; once president of the Morris County Medical Society; died January 14.

Laura House Branson * Iowa City; State University of Iowa, Iowa City, 1885; aged 50; formerly a member of the staff of Mercy Hospital, Iowa City, and president of Johnson County Medical Association, and the Iowa Women's Medical Society; died at the home of her daughter in Oklahoma City, January 11.

John Willcheur Barnes, Columbus, Ohio; Cincinnati College of Medicine and Surgery, 1889; aged 56; formerly demonstrator of anatomy and later professor of practical anatomy in the Medical College of Ohio, Cincinnati; died January 1, from diphtheria.

Henry Neill Dickson * Paragould, Ark.; Vanderbilt University, Nashville, Tenn., 1889; aged 52; pathologist and physician to the Paragould Sanitarium; died in St. Louis, December 7, from peritonitis following rupture of the gall-bladder.

Joseph Eugene Rolly Ellis, Grafton, W. Va.; Bellevue Hospital Medical College, 1895; aged 48; a member of the

West Virginia State Medical Association; a veteran of the war with Spain; died December 22, from heart disease.

Dudley W. Stewart, Los Angeles; Northwestern University Medical School, Chicago, 1861; aged 83; a pioneer practitioner of Southern California; surgeon of United States Volunteers during the Civil War; died about January 1.

David S. Alverson, Vicksburg, Miss.; Memphis (Tenn.) Hospital Medical College, 1899; aged 44; a member of the Mississippi State Medical Association; was shot and killed, it is believed, by the husband of a patient, January 5.

Franklin Loder, Logansport, Ind.; Indiana Eclectic Medical College, Indianapolis, 1890; aged 55; died in St. Joseph's Hospital, Logansport, December 30, from the effects of poison, taken, it is believed, with suicidal intent.

George William Fox * Milwaukee; Rush Medical College, 1897; aged 44; a well known surgeon of Milwaukee; for many years a member of the staff of St. Mary's Hospital; died January 8, from bronchopneumonia.

Frank C. Stewart, Indianapolis; Hahnemann Medical College, Chicago, 1886; aged 66; a member of the Medical Corps of the Indiana National Guard during the war with Spain; died January 1, from paralysis agitans.

Albert Chenoweth, Bushnell, Ill.; Rush Medical College, 1872; aged 71; formerly a surgeon in the Army, serving with General Reno at the time of the Custer massacre; died January 2, from cerebral hemorrhage.

Arthur Joseph Lance * Portsmouth, N. H.; University of Vermont, Burlington, 1893; aged 49; a member of the American Academy of Ophthalmology and Oto-Laryngology; died January 4, from cerebral hemorrhage.

Oscar Wilhelm Carlson, Milwaukee; Hahnemann Medical College, Chicago, 1872; aged 76; a practitioner for fifty-four years; a veteran of the Civil War; a member of the staff of St. Mary's Hospital; died January 7.

Charles Freemont Darnall * Llano, Texas; Rush Medical College, 1882; aged 63; secretary of the Llano County Medical Society, and city health officer; died December 2, from chronic bronchitis.

Alfred Manic Sharrocks, Syen Chyun, Chosen, Korea; Cooper Medical College, San Francisco, 1899; aged 47; died in Rochester, Minn., December 25, from atrophic cirrhosis of the liver.

Monroe Jacob Holben, Slatington, Pa.; Hahnemann Medical College, Philadelphia, 1875; aged 69; a member of the town council of Slatington; died December 17 from neurasthenia.

Laris P. Torrence * Blakesburg, Iowa (license, Iowa, years of practice, 1886); aged 72; a practitioner for forty-five years; died in Ottumwa, Iowa, January 8, after a surgical operation.

Elbridge Olin Kinne, Syracuse, N. Y.; University of Michigan, Ann Arbor, 1878; aged 67; consulting physician to the Homeopathic Hospital; died January 4, from heart disease.

Charles Russell Cavanagh, Boston; Harvard University Medical School, 1892; a member of the Massachusetts Medical Society; died at his home, in Dorchester, Boston, recently.

John T. McClanahan, Boonville, Mo.; Eclectic Medical Institute, Cincinnati, 1874; aged 66; at one time a member of the state medical board of Missouri; died January 1, from paresis.

Lewis Calvin Emenhiser * Indiana Harbor, Ind.; Chicago College of Medicine and Surgery, 1915; aged 32; died in the Presbyterian Hospital, Chicago, January 2, from encephalitis.

Frank Merle Dryden, Chicago; University of Illinois, Chicago, 1919; aged 30; died in Wesley Memorial Hospital, Chicago, December 28, from septicemia following a carbuncle.

Henry L. J. Hille, Roaring Spring, Ky. (license, examination and twenty-three years practice, 1894); aged 69; died at the home of his son-in-law, January 3, from heart disease.

James E. Morrison, Boulder, Colo.; Hahnemann Medical College, Chicago, 1866; aged 85; for many years a practitioner of Paxton and Urbana, Ill.; died January 1.

Benjamin Sindel * New York City; Long Island College Hospital, Brooklyn, 1907; aged 34; assistant surgeon to the Gouverneur Dispensary; died January 7.

Carl Elias Dufft, Mount Vernon, N. Y.; College of Physicians and Surgeons in the City of New York, 1881; a well known vocalist; died January 9.

* Indicates "Fellow" of the American Medical Association.

Claudius G. Barnett, Lewisville, Ind.; Medical College of Ohio, Cincinnati, 1877; aged 64; a member of the Indiana State Medical Association; died, December 28, from arteriosclerosis.

Francis Thornton Buckner, Kansas City, Mo.; Bellevue Hospital Medical College, 1865; aged 83; a Confederate veteran; died in a hospital in Kansas City, December 27.

Harry Wadsworth Dorman, St. Petersburg, Fla.; Western Reserve University, Cleveland, 1881; aged 67; for many years a practitioner of Ashtabula, Ohio; died January 4.

Homer Corby Rice, New Freeport, Pa.; University of Pittsburgh, 1897; aged 50; a member of the Medical Society of the State of Pennsylvania; died December 24.

Ralph W. Connell, Omaha; Pulte Medical College, Cincinnati, 1882; aged 60; formerly health commissioner of Omaha; died January 3, from heart disease.

Edwin Alphonso Carpenter, Baileyville, Ill.; Rush Medical College, 1875; aged 73; a practitioner for 52 years; a veteran of the Civil War; died December 31.

Charles T. Morel de la Durantaye, Bourbonnais, Ill.; Ecole de Médecine et de Chirurgie, Montreal, 1888; aged 61; died January 5, from heart disease.

Daniel Heard Brook, Lieut., M. C., U. S. Army, Travis, Texas (license, Texas State Board, 1907); died December 22 from chronic interstitial nephritis.

Homer Andrew Bushnell, North Adams, Mass.; Albany (N. Y.) Medical College, 1905; aged 41; died in a sanatorium at Westfield, Mass., December 31.

Edward William McBirney, Willet, N. Y.; University of the City of New York, 1875; aged 69; health officer of Cortland County; died December 19.

Ezra Albert Scammon, Columbus, Kan.; University of Michigan, Ann Arbor, 1867; aged 76; also a druggist; died December 30, from pneumonia.

Addison Marshall Clark, Youngstown, Ohio; University of Pennsylvania, Philadelphia, 1880; aged 62; died December 22, after a surgical operation.

Jennie Lind Phillips Thompson, Chicago; University of Illinois, Chicago, 1898; aged 51; died January 4, from cerebral hemorrhage.

John Pressly Logan, Ottawa, Kan.; Medical College of Ohio, Cincinnati, 1867; aged 77; died January 1, from cerebral hemorrhage.

Theophilus W. Hunter, Quitman, Ga.; Jefferson Medical College, 1876; aged 68; died in a sanitarium in Atlanta, December 13.

Frank A. Maguy ♂ Chicago; Hahnemann Medical College, Chicago, 1890; aged 61; died December 29, from bronchial pneumonia.

W. S. Barton, Orangeburg, S. C.; Reform Medical College, Macon, Ga., 1860; aged 81; died November 23, from pleuropneumonia.

Franklin Bennett, Brooklyn, N. Y.; University of the City of New York, 1875; aged 70; died December 28, from pneumonia.

John Delmayne Hanson ♂ Donaldsonville, Ind.; Tulane University, New Orleans, 1880; aged 70; died about January 5.

Edgar Henry Byers, Philadelphia; Jefferson Medical College, 1889; aged 54; died January 7, from a nervous breakdown.

Thomas E. Russell, Paducah, Ky.; University of Louisville, Ky., 1886; aged 58; died December 31, from paralysis.

John Milton French ♂ Silsbee, Texas; University of Nashville, Tenn., 1903; aged 41; was found dead, December 11.

Leonora Elma Knerr, Indianapolis; Medical College of Indiana, Indianapolis, 1898; aged 68; died December 14.

Oscar M. Long, Columbia, Mo.; University of Louisville, Ky., 1892; aged 50; died December 29 from tuberculosis.

Almanzer Ronelson Howard, Canton, Ill.; Eclectic Medical Institute, Cincinnati, 1878; aged 59; died December 23.

James Hamilton Cummins, Newark, N. J.; Bellevue Hospital Medical College, 1890; aged 57; died December 4.

Howard Judson Denovan, Stettler, Alta.; Trinity Medical College, Toronto, 1892; aged 51; died November 16.

Abel Roberts Wilson, West Albany, Ala. (license, Lawrence County, Ala., 1885); aged 82; died December 22.

Frank Duncan, Paxton, Ill.; Hahnemann Medical College, Chicago, 1875; aged 71; died January 1.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

APOTHELINE

Report of the Council on Pharmacy and Chemistry

Apothesine is a synthetic drug for producing local anesthesia, made by Parke, Davis & Company. In the fall of 1917 the Council wrote to Parke, Davis & Company offering its aid in establishing the identity, purity, and therapeutic efficiency of this synthetic local anesthetic with the ultimate object of accepting the product for inclusion in New and Nonofficial Remedies should the facts warrant such acceptance. The Council's letter was never acknowledged. After Apothesine was put on the market the Council desired to accept it for inclusion in New and Nonofficial Remedies but, unfortunately, was unable to do so because some of the claims made for the product were not justified by acceptable evidence. The manufacturers were notified of the Council's desire to admit this product to N. N. R. and the wish was expressed that the company would either so modify its claims as to make the product acceptable under the Council's rules or else would submit evidence to the Council in proof of the claims made and thus permit the Council to revise its conclusions. Parke, Davis & Company were, apparently, either unwilling or unable to submit evidence that would sustain their claims; neither did they offer to modify the claims themselves. The product, therefore, is ineligible to inclusion in New and Nonofficial Remedies; it will, however, be listed in the "Described But Not Accepted" department of New and Nonofficial Remedies. The report on Apothesine that follows has been authorized for publication.

W. A. PUCKNER, Secretary.

Apothesine, "the hydrochlorid of diethyl-amino-propylcinnamate," is an efficient local anesthetic. It belongs to the procain rather than to the cocain type, that is, it belongs to that type which, while effective for injection anesthesia (especially when combined with epinephrin) is relatively inefficient when applied to mucous membranes. Apothesine may also be used for spinal anesthesia. Its absolute toxicity is less than that of cocain (as 20 is to 15, see table below) but about twice that of procain (as 20 is to 40, see table below). It is non-irritant, is easily soluble and makes a stable solution so that it may readily be sterilized.

The Council took exception to certain claims made by Parke, Davis & Company for their product on the ground that these claims were not supported by acceptable scientific evidence. One of the claims was that Apothesine is applicable in any case in which any other local anesthetic is used. This statement, made in many advertisements, is distinctly misleading as used. When applied to mucous membranes Apothesine is far inferior to cocain and to some other local anesthetics, yet the claim obviously suggests that Apothesine is an efficient substitute for any local anesthetic.

The manufacturers claimed, too, that Apothesine is as potent as cocain. The claim would lead the physician to think that Apothesine had the same anesthetic potency as cocain in solution of equal strength. This statement, so far as it refers to the drug when applied to mucous membranes, is not in accord with the facts and is true for injection anesthesia only when stronger solutions are used. The only support for the claim of equal efficiency appears to be the experiments with intracutaneous injections made by H. C. Hamilton¹ in Parke, Davis & Company's laboratory. These

1. The Comparative Values of Some Local Anesthetics by H. C. Hamilton, Detroit, Mich., from the Research Laboratory of Parke, Davis & Co., J. Lab. & Clin. M. 4: 60 (Nov.) 1918.

differed considerably from the results of Sollmann.² A further series of experiments were made by Sollmann to compare still further the diverse results previously reported by him and Hamilton. The latest series, while showing considerable variations in the susceptibility of different skin areas, especially toward Apothesine, demonstrated in every case that the efficiency of Apothesine is unmistakably lower than that of cocaine, being at best one half. The series also showed that the potency of Apothesine was never greater than procain and averaged considerably below it.

Another claim made for Apothesine which the Council holds is not supported by evidence is that of superior safety. This claim is made on the basis of hypodermic injections in guinea-pigs carried out in the laboratory of Parke, Davis & Company. Such experiments prove little because of the fact—well known to laboratory workers—that the use of rodents in toxicity tests made by injecting a drug into the subcutaneous tissues does not give a reliable index of the relative toxicity of such a drug for man. This is due partly to the peculiar resistance of rodents to poisons and partly to the great importance of the rate of absorption. The organism destroys most local anesthetics so rapidly that the rate of absorption is more important than the absolute dose. The absorption from hypodermic injections into guinea-pigs differs, of course, from that in clinical accidents, especially where the drug has been applied to mucous membranes. One cannot, therefore, reliably estimate the degree of clinical danger on animals.

It has been shown that when toxicity tests of local anesthetics are made on cats these animals seem to respond to the drugs in a manner more closely approximating humans and it is a suggestive fact that the more toxic of local anesthetics, as shown by tests on cats, have been found the most dangerous in clinical use. The *absolute* toxicity of Apothesine has been measured by Eggleston and Hatcher³ by the intravenous injection in cats. The fatal doses, in terms of milligrams per kilogram ranged as follows:

Alypin, Holocain.....	10
Beta Eucaïn.....	12.5
Cocain.....	15
Apothesine.....	20
Tropacocain.....	20—25
Stovain.....	25—30
Nirvanin.....	30—35
Procain.....	40—45

The *absolute* toxicity of Apothesine is, therefore, only a little lower than that of cocaine, and is twice as great as that of procain. The *clinical* dangers cannot be predicted by either method, since clinical accidents depend, in most instances, on idiosyncrasies, or the technic of application.

DIAL "CIBA"

Report of the Council on Pharmacy and Chemistry

Dial "Ciba" has not been accepted for "New and Non-official Remedies" because, as the report which follows shows, unwarranted claims are made for the product. It is a definite new chemical compound which might be made eligible for N. N. R. if misleading therapeutic claims were eliminated. The Council directed that Dial "Ciba" be included with Articles Described but Not Accepted, so that physicians might be informed with regard to its character and properties.

W. A. PUCKNER, Secretary.

Dial "Ciba" is a hypnotic manufactured by the Society of Chemical Industry of Basle, Switzerland, and is sold in the United States by A. Klipstein and Company, Inc., New York. Chemically, Dial "Ciba" is diallylbarbituric acid and is,

therefore, closely related to diethylbarbituric acid or barbital ("veronal").

The claims made for Dial "Ciba" are (1), that the "allyl" group in its molecule makes it more readily decomposed by oxidizing agents than barbital, which contains the "ethyl" group; (2) that because of this ease of oxidation, it is more readily decomposed in the body and more rapidly and completely eliminated, and (3) that because of its alleged rapid elimination, it is devoid of the after effects of barbital and other hypnotics.

The Council took up the substance in February, 1918, and referred the matter to the referee in charge of barbital preparations. The referee considered unwarranted the claim that Dial "Ciba" did not have the after-effects of other hypnotics due to its alleged total decomposition in the body. The American agents, A. Klipstein and Company, were informed of the referee's objections. Their attention was also called to the fact that, notwithstanding the claimed absence of after-effects in one part of the advertising, other parts of the same advertising admitted certain post-hypnotic effects of the product. It was pointed out also that while it was claimed in one of the advertising circulars that lowering of the blood pressure is never observed after administration of Dial "Ciba," yet two of the authors quoted in the same circular definitely stated that a lowering of the blood pressure followed even small doses of the drug and these authors warn against this very danger in certain conditions.

A year later, a circular letter sent out by A. Klipstein and Company reiterated the claim that the asserted decomposition of Dial "Ciba" in the body prevents after-effects, the drug being still contrasted with barbital ("veronal"). In view of the reiteration of this highly improbable claim, the referee undertook to study the comparative action of Dial "Ciba" as compared with other hypnotics. It was found that the actions of Dial "Ciba" are not distinguishable, qualitatively, from those of barbital, there being no perceptible difference in the after-effects or in the nature of the side actions. In toxic doses, both caused profound depression with the temperature falling to that of the room (or about one degree above), the respiration being extraordinarily slow and shallow as one would expect with lowering of the temperature. There were also the same evidences of nausea that are so frequently seen after toxic doses of the various hypnotics of this group. In view of these results, the Council declared that it is unwarranted to claim freedom from after-effects for Dial "Ciba."

The Council held that the following statement is unwarranted:

"The therapeutic field for Dial 'Ciba,' as shown by tests on rabbits, is just as broad as the field for Diethylbarbituric Acid."

Tests on rabbits do not and cannot show the breadth of the therapeutic field for a hypnotic. The Council also declared the following statement improbable, and contrary to the evidence obtained by the referee:

"In dogs, the increase of dosage beyond the therapeutic dose to the point of death is decidedly in favor of Dial 'Ciba,' which required a larger dose [than diethylbarbituric acid] to produce death."

The referee's experiments on cats show that Dial "Ciba" is several times as toxic as hydrated chloral, and more than twice as toxic as diethylbarbituric acid (barbital).

Since the circular to which objection was made in 1918 was still being sent out in December, 1919, the Council held Dial "Ciba" inadmissible to N. N. R. and voted that report of its action in the matter be authorized for publication. The Council further directed that Dial "Ciba" be included with Articles Described but Not Accepted.

Diphtheria Carriers.—The person attending the patient should wear a double layer of gauze or other soft thin cloth across the mouth and nose as a face mask whenever near the patient so as to prevent the droplets containing the germs coming from the patient's mouth from entering and lodging on the mucosa of the mouth and throat of the attendant. Even though you may not contract the disease if the bacteria lodge in your throat, they may grow there and you may act as a carrier and thus spread the disease to others.—Keep Well Series No. 4, U. S. P. H. S.

3. A Further Contribution to the Pharmacology of the Local Anesthetics by Eggleston and Hatcher, from the Department of Pharmacology, Cornell University Medical College, New York City, J. Pharmacol. & Exper. Therap. **13**: 433 (Aug.) 1919.

Correspondence

"AMPUTATION ABOVE THE LEVEL OF ARTERIAL OBSTRUCTION IN ARTERIOSCLEROTIC GANGRENE"

To the Editor:—In THE JOURNAL, Dec. 6, 1919, p. 1760, Drs. Eisendrath and Bettman suggested that in arteriosclerotic gangrene (thrombo-angiitis obliterans) it would be advisable to amputate above the level of arterial obstruction, such obstruction to be determined by preliminary exposure of the femoral artery. It is recommended that the artery be ligated in its pulsating portion, and that amputation be performed at the same level. Reference is made to a case in which this was done, and diagrams show the presence of a thrombus in the common femoral artery and the point of ligation above the thrombus just below Poupart's ligament. In spite of the high amputation, there was some gangrene of the flaps.

This condition is one in which the surgeon after the operation frequently feels that whatever may have been the level he has chosen for the amputation, he has erred. If he obtains primary union without gangrene of the flaps, he wonders if possibly he has not made his amputation too high; and if gangrene of the flaps results, he thinks he should have amputated at a higher level.

In an amputation of the thigh below the hip, the question of a few inches more or less of stump is of extreme importance. It is generally conceded that amputation higher than 3 inches below the great trochanter is almost worse than useless from the standpoint of hip motion of an artificial limb, so that the surgeon should in every case make a strenuous effort to get a stump of satisfactory length. I have amputated in the middle of the thigh, and have been compelled to reamputate a few inches of stump because gangrene of the flaps did not leave sufficient skin to cover over exposed bone; but even after the secondary operation, the length of the stump was satisfactory. Sight is lost of the fact that this is a chronic condition affecting chiefly main trunks and their terminal branches, and that a fair collateral circulation is established before the patient is operated on. Were this not so there would frequently be complete gangrene of the leg, something I have never seen in this condition. The superficial femoral artery and its terminals, the anterior and posterior tibials, are often occluded, the deep femoral (profunda) rarely. It is this artery with its branches that will usually take care of the nourishment of a fair sized thigh stump. I am of the opinion that had the amputation in the case mentioned been a few inches lower, leaving the profunda (which in the diagram is free of thrombus) to take care of the circulation, no gangrene of the flaps would have occurred, and the patient would have had a serviceable stump, which today he probably has not; even if some gangrene of the flaps had occurred, the amount of limb that had to be sacrificed in a reamputation might still have been so small that the final result would have been good.

I have amputated below the knee, when there was no pulsation distal to the common femoral, and when permission to do a primary high amputation could not be obtained; in spite of complete occlusion of the anterior tibial with practically no bleeding from any part of the cut surface, I have frequently had satisfactory healing of the stump.

Primary union is something to be hoped for in these cases, but not expected as a routine. End-results count; and if for the sake of obtaining primary union without any gangrene of flaps we sacrifice length of stump when length is important, as in the upper thigh, the patient suffers.

That a thrombus from the femoral may extend into the iliac and thence to the iliac of the other side is, of course, a possibility. Dr. Eisendrath mentions such a case, but this complication must be so rare as hardly to enter into the formation of a judgment as to the proper level for amputation.

Bearing on the subject, I wish to refer to a case in which I recently operated for gangrene of the foot, with no pulsation lower than the common femoral. The patient requested

amputation below the knee, with the understanding that if after doing this I thought it necessary to reamputate higher, I might do so. On amputation below the knee there was absolutely no bleeding. Both tibials were firmly occluded. I then amputated through the thigh about 8 inches below the hip and found the superficial femoral artery completely occluded. There was, however, some bleeding from branches of the deep femoral artery, not enough to make one sanguine of the result; but I preferred to chance it rather than go higher and get a useless stump. The result was all that could be desired, healing being by primary union. It seems to me that in these conditions it pays to give nature a chance, or, to put it another way, it pays to let the patient run a little extra risk.

LEO B. MEYER, M.D., New York.

THE PERCENTAGE OF NECROPSIES

To the Editor:—There were two interesting communications in THE JOURNAL, Dec. 6 and Dec. 27, 1919, by Drs. Francis Carter Wood and Joseph C. Doane, respectively, relative to the low percentage of necropsies performed in our large hospitals, following the interesting paper, Sept. 20, 1919, by Douglas Symmers. The following report for the year 1919 from the City and County Hospital, St. Paul, shows that there are some hospitals which have a fairly high percentage of necropsies: total number of deaths during 1919, 608; necropsies granted by the coroner, 29; by permission from relatives obtained by the superintendent, 61; by permission obtained from relatives through the house physician, house surgeon and assistant superintendent, 154; total number of necropsies performed, 244; percentage of necropsies performed, 40.1 + per cent.

G. B. KRAMER, M.D., St. Paul.

Resident Pathologist, City and County Hospital.

ADDISONISM

To the Editor:—This affection has been included under the general term chloasma; yet though it may be a form of this, it is of so definite and specific a nature that it deserves to be considered as a special entity. In Sutton's "Diseases of the Skin," page 494, there is an illustration of this condition as an unusual type of chloasma. In this affection, as the name implies, certain portions of the face acquire a pigmentation akin to the bronzing of Addison's disease, but limited in its distribution and varying in its tint from light fawn to a dark tan. The characteristic feature of this pigmentation is its symmetrical distribution, most commonly limited to the cheeks on and external to the malar prominences. In well marked cases the pigment is also deposited in semilunar patches above the eyebrows, conforming to their lines and connecting in the median line with a central frontal patch, while from another patch in the center of the chin there extends a circumoral ring.

The local treatment does not differ from that for chloasma and need not be discussed, as the interest of this affection lies in its probable etiology.

I have assumed that we have here a pigmentation that is an expression of hypoadrenalism, and in a form by no means rare. On an average, three or four cases a year come under observation, and all thus far have been in females. Careful inquiry into the history of the last twelve cases shows that four of the patients were affected with hereditary syphilis; four with tuberculosis, at present latent; two showed evidence of malnutrition but no evident disease, and two were apparently healthy. Their ages ranged from 11 to 23 years, and the pigmentation had been present from six months to three years. The color is usually deposited slowly, but may appear somewhat suddenly, as in one instance in which it became apparent one week after a severe tonsillar operation. How long it may persist when left to nature I am unable to say, as all I have seen have come for the removal of the pigment.

The association of Addison's disease with tuberculosis is well established; but whether addisonism is due to actual

tuberculous deposits in the suprarenals or is the result of diminished function consequent on the toxemia has yet to be determined.

The syphilitic cases are interesting, as we have here an expression of pigmentation that is probably akin in its origin to the coppery pigmentation characteristic of the acquired disease. It seems highly probable that the pigmentation in acquired syphilis is wholly due to the disease inhibiting the normal secretion of the suprarenals.

In a leading article in *THE JOURNAL*, Nov. 29, 1919, attention was called to experiments that suggest that arsenic has a selective action on the suprarenals, and proof of this is afforded by the occasional occurrence of typical Addison's disease after arsphenamin injections. Color is further lent to this probability by the frequent appearance of increased pigmentation around syphilitic lesions in the arsenical treatment of syphilis.

ANSTRUTHER DAVIDSON, M.D., Los Angeles.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

RECENT LITERATURE ON SOCIAL MEDICINE AND SOCIAL INSURANCE

To the Editor:—I am wondering whether it is consistent for me to request of you references to the leading articles on social medicine and medical insurance which have appeared during the past year. Where can I find a good discussion of the work of the medical insurance act in England?

JOHN SUNDWALL, M.D., Minneapolis.

ANSWER.—The following articles on social medicine have appeared in current medical literature for the past year:

- Wortman, J. L. C.: Reform in Social Medicine, *Nederlandsche Tijdschr. v. Geneesk.* **2**:1675 (Nov. 23) 1918.
Sand, René: Rise of Social Medicine, *Mod. Med.* **1**:189 (July) 1919.
Glaister, J. N.: A State Medical Service, *Lancet* **197**:751 (Oct. 25) 1919.
Fairfield, W. E.: Business Evolution and the Future of Private Medical Practice, *Illinois M. J.* **36**:250 (Nov.) 1919.

The following articles on health insurance have appeared in current medical literature in 1919:

- Whalen, C. J.: Health Insurance, *Illinois M. J.* **35**:1 (Jan.) 1919.
Stern, Isadore: Health Insurance, *Pennsylvania M. J.* **22**:391 (March) 1919.
Hoffman, F. L.: Health Insurance and the Public, *Pennsylvania M. J.* **22**:664 (July) 1919.
Rott, O. M.: Arguments Against Compulsory Health Insurance, *Northwest Med.* **18**:81 (May) 1919.
Ballinger, J. R.: Compulsory Health Insurance, *Illinois M. J.* **35**:9 (Jan.) 1919.
Fairhall, Joseph: Compulsory Health Insurance, *Illinois M. J.* **35**:12 (Jan.) 1919.
Ochsner, E. H.: Compulsory Health Insurance, *Illinois M. J.* **35**:3 (Jan.) 1919.
Verney, L.: Health Insurance in Different Countries, *Policlinico (sez. prat.)* **26**:817 (June 29) 1919.
Lapp, J. A.: Health Insurance, Its Disadvantages and Advantages, *Pennsylvania M. J.* **22**:661 (July) 1919.
Warren, B. S.: Health Insurance, Medical Profession and Public Health, Including Results of Study of Sickness Expectancy, *Pub. Health Rep.* **34**:775 (April 18) 1919.
Harris, M. L.: National Health Insurance, *Illinois M. J.* **35**:10 (Jan.) 1919.
Cunningham, W. P.: Health Insurance, Socialistic Subjugation of Medical Profession, *Delaware State M. J.* **10**:8 (April-June) 1919.
Downing, A. F.: Study of Health Insurance in Relation to History of Two Countries Where It Has Found Most Favor, *Boston M. & S. J.* **180**:433 (April 17) 1919.
Stanton, E. M.: Compulsory Health Insurance: Its Promises and Its Dangers, *Med. Rec.* **96**:749 (Nov. 8) 1919.

In addition to the literature for the past year, the following articles and pamphlets will be of interest to the student of health insurance:

Social insurance pamphlets issued by the Council on Health and Public Instruction of the American Medical Association, 535 North Dearborn Street, Chicago:

Pamphlet I. Workmen's Compensation Laws, from the Report of the Judicial Council of the American Medical Association for 1915.

Pamphlet II. Social Insurance, the Report of the Special Committee of the American Medical Association for 1916.

Pamphlet VI. Medical Organization Under Health Insurance, by Dr. Alexander Lambert, New York.

Pamphlet VII. Statistics Regarding the Medical Profession, compiled by the Committee on Social Insurance.

Pamphlet XI. Social Insurance, Report of the Special Committee of the American Medical Association for 1919.

Reports of special commissions on social insurance. (These may be secured by writing to the secretary of the committee at the state capital).

Report of the Massachusetts Special Committee on Social Insurance, February, 1917, House Document 1850; Jan. 15, 1918, Senate Document 244, Boston.

Report on Health Insurance by the New Jersey Commission on Old Age Insurance and Pensions, 1917.

Report of the Wisconsin Special Committee on Social Insurance, January, 1919, Madison, Wis.

Report of the Social Insurance Commission of the State of California, Sacramento, March, 1919.

VLEMINCKX' SOLUTION

To the Editor:—Will you please send me the prescription for Vleminckx' solution as used by Dr. William A. Pusey for verrucae and described by him in an article under Clinical Notes, etc., in *THE JOURNAL*, Jan. 10, 1920, p. 97? I am unable to find the liquid described in any of my textbooks on the skin.

H. W. KENFIELD, M.D., Lawrence, Mich.

To the Editor:—Will you kindly inform me what Vleminckx' solution contains?

F. J. W., Freeburg, Mo.

To the Editor:—Will you kindly forward me the formula for Vleminckx' solution?

J. L. DACH, M.D., Reeder, N. D.

ANSWER.—This solution appears in the National Formulary. It is also known as Liq. Calc. Sulphurat., the solution of oxysulphuret of calcium, and as Vleminckx' Lotion. It is made thus:

Calcium oxid	165 gm.
Sublimed sulphur	250 gm.
Water, the completed mixture to make....	1,000 c.c.

Shake the calcium oxid, mix it with the sulphur and add the mixture gradually to 1,750 c.c. of boiling water. Boil this mixture, with frequent agitation, until it is reduced to 1,000 c.c. and maintain this volume while boiling one hour, by the addition of water from time to time. Cool and strain

the mixture and having allowed the solution to become clear by standing in a stoppered bottle. decant the clear brown liquid, and preserve it in completely filled and well stoppered bottles.

"ALLEGED PLACENTAL FUNCTIONS"

To the Editor:—The editorial comment on "Alleged Placental Functions" (THE JOURNAL, Dec. 6, 1919, p. 1774) caused me to wonder whether any experiments had ever been made on the cow, which, being a herbivorous animal, eats the placenta immediately after its passage. It has always occurred to me that the cow must have good and sufficient reasons for doing this. L. C. AUDRAIN, M.D., Mazatlan, Mexico.

ANSWER.—It is generally known that rabbits, horses, pigs and cows eat the placenta. We are unable to find any references to experiments performed on these animals to demonstrate the effect that would follow if the animal should be prevented from eating the placenta. The subject is rather well summarized in THE JOURNAL, Jan. 3, 1920, p. 47. The United States Department of Agriculture, Bureau of Animal Industry, replies to the question, saying that one reason that leads certain animals to eat the placenta is an instinct to destroy this structure so as to leave no evidence of parturition. The eating is done as a matter of protection against predatory animals, and as an instinctive measure to keep such animals from locating the newly born young. It is also suggested that most animals are usually very hungry after parturition, and this perhaps explains why the placenta is eaten. On the whole, it may be said that the reason for eating the placenta has never been adequately demonstrated, and experiments on feeding placental tissue to human beings are very inconclusive.

TUBERCULOUS POULTRY

To the Editor:—Nov. 26, 1919, I bought a chicken (drawn) in a nearby market, and when it was dressed my attention was called to the size of the liver. On examination, both liver and spleen appeared to be tuberculous. A laboratory report shows tubercle bacilli from both organs. The chicken was sold for a spring hatched bird.

E. C. McGEHEE, M.D., Stevenson, Minn.

ANSWER.—This phase of meat inspection has not been given special attention by the United States government or by most city departments of health, probably for the reason that a tremendous force would be necessary to inspect dressed chicken that came to the market. The transmission of tuberculosis from fowls to man is practically negative, owing to the fact that proper cooking renders the fowl, if affected, harmless. It seems likely that almost any housewife would notice marked tuberculosis in the livers of poultry being prepared for the table.

Chicago has a city ordinance, which reads:

No cased, blown, plaited, raised, stuffed, putrid, impure, unhealthy, or unwholesome meat, fish, bird or fowl shall be held, bought or sold or offered for sale for human food, in any place in said city. Every person or corporation who shall violate any of the provisions of this section shall be fined not less than twenty-five dollars nor more than one hundred dollars for each offense.

BLACK TONGUE

To the Editor:—What is the treatment of black tongue (nigrities linguae)? J. L. RAVITT, M.D., Montezuma, Iowa.

ANSWER.—The cause of the condition is unknown. No pathogenic organism has been found to account for it. It usually disappears spontaneously in time. It may last for only a few weeks or a few months, or it may persist for years. Cleanliness and antiseptic mouth washes may be of service. Nothing is gained by scraping or destroying the elongated papillae. Such measures simply produce apparent benefit by getting rid for the time being of the cause of the blackness.

LEGAL DECISIONS ON BURNS FROM HOT-WATER BOTTLE

To the Editor:—I have a case coming up in court next June, in which it is alleged that a patient in my hospital was burned by a hot-water bottle. It is quite similar to the one published in THE JOURNAL, Dec. 27, 1919. I would appreciate it very much if you will refer me to other cases that have been published in which the supreme court decision is similar. X. Y. Z.

ANSWER.—Reports of decisions on similar cases were published in THE JOURNAL, March 8, 1919, p. 754; June 9, 1917, p. 1775; April 8, 1916, p. 1162, and Nov., 2, 1912, p. 1650.

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

ALASKA: Juneau, Mar. 2. Sec., Dr. L. O. Sloan, Juneau.
CALIFORNIA: Los Angeles, Feb. 16-19. Sec., Dr. Chas. B. Pinkham, 906 Forum Bldg., Sacramento.
CONNECTICUT: New Haven and Hartford, March 9-10. Sec., Reg. Bd., Dr. Robert L. Rowley, Hartford. Sec., Homeo. Bd., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven. Sec., Eclectic Bd., Dr. James Edwin Hair, 730 State St., Bridgeport.
ILLINOIS: Chicago, Mar. 1-3. Director, Mr. Francis W. Shepardson, Springfield.
INDIANA: Indianapolis, Feb. 10-13. Sec., Dr. W. I. Gott, 84 State House, Indianapolis.
KANSAS: Topeka, Feb. 10. Sec., Dr. H. A. Dykes, Lebanon.
MAINE: Portland, March 9-10. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.
MASSACHUSETTS: Boston, March 9-11. Sec., Dr. Walter P. Bowers, Room 144, State House, Boston.
NATIONAL BOARD OF MEDICAL EXAMINERS: St. Louis and Chicago, Feb. 18-25. Sec., Dr. J. S. Rodman, 1310 Medical Arts Bldg., Philadelphia, Pa.
NEW HAMPSHIRE: Concord, March 11-12. Sec., Dr. Charles Duncan, Concord.
NEW YORK: New York City, Albany, Buffalo, Jan. 27-31. Asst. Professional Examinations, Mr. H. J. Hamilton, Albany.
VERMONT: Burlington, Feb. 10-12. Sec., Dr. W. Scott Nay, Underhill.
WYOMING: Thermopolis, Feb. 2-4. Sec., Dr. J. D. Shingle, Cheyenne.

PLUMBOPATHY

A Satire on Cults in Medicine

The editor of the Fresno (Calif.) *Republican*, some six months ago, evidently feeling in a pleasantly bitter mood, took his pen in hand and turned out the following comment on the new school of plumbopathy:

"PLUMBOPATHY"

"We rise again to protest! Examinations were held in Fresno last night for plumbers' licenses. No one is permitted to practice plumbing in California without such a license. And all the examinations are in the complete control of the regular or plumbopathic school. This is a rank discrimination against the disciples of other plumbing faiths.

"The plumbopathic school, for instance, holds to the doctrine that air has pressure, and that an air outlet, properly connected, is therefore necessary behind every water seal, to keep the pressure on the two sides equal. Shall persons who do not believe in air pressure be deprived of their constitutional liberty to choose a plumber of their own suckopathic school, who will make the connections all the way to the sewer unvented, to increase the suction? The plumbopaths also believe that when the water stops running from a faucet, there is some obstruction in the pipe leading to that faucet. Shall we give them the legal right to exclude from practice the aeroplumbos, who teach that it is due to the wind blowing in the wrong direction? When the pipe joints leak, also, it is plumbopathic therapy to repack the screw threads with red lead. Shall this procedure be imposed on a householder who believes that they ought, instead, to be packed in ice, to contract the metal, and shall he be denied his liberty to call in a practitioner of the gelopathic school?

"Moreover, why should plumbers be examined on their practical knowledge of pipes and metals and joints, and of the legal requirements for installing them? These pipes and joints are not the ultimate Truth of plumbing. They are merely its proximate manifestations. On the plane of the Absolute, all Plumbing is Water. The ingress and egress of Water is the Supreme Significance of Plumbing. But water is no mere immediate Fact. It is derived from the melting snows of the Providential Mountains, or from the raindrops of the Heavenly Clouds. And these are but manifestations of the Force of the Sun. Therefore, considered absolutely, and not relatively, water is Sun, Helios. Shall the practitioners of Heliodic Science be required to divert their attention from these high contemplations to mere material pipes and wrenches, as a condition of treating errors of plumbing by Heliogenic absent treatment?

"We suggest that the dissenting plumbers and their potential customers form a League for Plumbing Freedom, to demand of the legislature equal recognition for all schools of plumbing, and especially to exempt from examination on the theory and practice of plumbing all persons who have conscientious scruples against such knowledge, and who believe that plumbing can be done better without it."

Presumably the powers that he could not see the matters in the same way that our editorial colleague sees it. So recently he has again dipped his pen in a well of gall and wormwood:

"UNJUST DISCRIMINATION"

"We are moved once more to register our annual protest against the pending examinations for plumbers' licenses. It is seriously proposed that no one shall practice plumbing in Fresno unless he knows plumbing, and that his competency shall be established by examination before a sectarian board, all of whose members but one are orthodox plumbers, and that one is an educated physician.

"What chance has a graduate of the aeropractic correspondence school of plumbing before such a board? There should be a referendum to the people, on a law authorizing the aeropractors to license themselves, on such educational qualifications as they are able to come up to. What right have these orthodox plumbers to examine candidates on hydrostatics and sanitation, or to test their knowledge of pipes and fixtures, or their skill in installing and repairing them? The aeropractors have testimonials showing a lot of people who never had any orthodox plumbing in their houses, and are still alive. Is it not an interference with religious liberty to confine the practice, in Fresno, to the one sect which knows pipes, fixtures and sanitation, and does its work with trained skill and in accordance with the ordinances?

"It is not the rights of the aeropractors alone that are involved. Even they are relatively materialists. Since the purpose of plumbing is to remove stench, their technic is to let the wind blow it away, or to install electric fans to help out the wind, in closed places. But there are more spiritual practitioners of the plumbing art who demonstrate that there is no such thing as stench. Stench is a sensation; not a fact. Sensation is a function of the mind. And since stench is a disagreeable sensation, it may exist in the mind but not in Mind. The remedy, therefore, is to raise mind to Mind, by the perusal of the textbook on Spiritualized Sanitation. This proposed plumbing examination is an intrusion on the liberty of conscience of all disciples of the Spiritual Sanitarians.

"If there is to be any such arbitrary requirement, we submit that there should be provision for a certificate of conscientious objection for those who do not wish to comply with it. Otherwise we shall be discriminating unjustly in favor of educated plumbers, by requiring education of their competitors. An educational qualification is undemocratic, in a community in which there are more people who do not know plumbing than there are who do know it. Let the majority rule!"

May we add our mild protest to what our colleague has written. Plumbing should not be restricted to the few. We demand the right to use our own system of intensive mental plumbing. If our pipes freeze up and break and we want to give Nature a chance to heal the wound, we object to having Mr. Dingbat, on the floor below, come up and complain that the secretions are dripping into his baby's bed and the child cannot sleep. There is such a thing as individual freedom and justice in this world, and we propose to have it.

California June Examination

Dr. Charles B. Pinkham, secretary of the California State Board of Medical Examiners, reports the oral and written examination held at San Francisco, June 23-26, 1919. The examination covered 9 subjects and included 90 questions. An average of 75 per cent. was required to pass. Of the 80 candidates who took the physician's and surgeon's examination, 65, including 1 osteopath, passed, and 15, including 7 osteopaths, failed. Seventy-seven candidates were licensed by reciprocity. Two candidates were granted osteopathic reciprocity certificates. One candidate received a drugless healer license, and 9 candidates were granted licenses to practice chiropody. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent

E. M. STANTON, M.D.

SCHENECTADY, N. Y.

The fact that the medical profession of New York State and of the entire country is a practically unanimous unit in condemning compulsory health insurance bills of the type proposed by the American Association for Labor Legislation is almost prima facie evidence that the great majority of practitioners realize more or less clearly that there is something fundamentally wrong with the project.

If we are to oppose compulsory health insurance we must be able to formulate our objections into definite terms, and it is my object in this paper to outline some of the more fundamental objections to compulsory health insurance. The time allowed will permit of my taking up only one or two of the defects which are inherent in the proposed legislation. I shall, however, attempt to show that some of the defects are so fundamental as to be inseparable from the entire problem of sickness insurance, be it intended for the rich or for the poor. I believe that it can be very clearly shown that when we talk about fire, life or marine insurance we are talking about insurance the value of which is self-evident to all who have studied the question; and, on the other hand, it should be equally clear that when we approach the subject of sickness insurance we encounter economic problems so entirely different from those encountered in standard insurance propositions that the very name of insurance is scarcely applicable in the field of so-called health insurance. In this connection, it is well to note that the so-called experts of the American Association for Labor Legislation have for at least six, and probably ten, years been struggling with the problem of trying to devise a workable bill, and that to date they have made a complete failure. This in itself should be at least presumptive proof that there may be something radically wrong with the materials with which they are trying to work.

STANDARD INSURANCE PROPOSITIONS

The proponents of compulsory health insurance tell us that fire insurance and life insurance are recognized as being of the very greatest economic and social value and that, therefore, health insurance is equally valuable. The fact remains, however, that up to the year 1919 sickness insurance has not been able to take its place alongside of fire and life insurance. There must be some good reasons why sickness insurance has always remained a weak sister in the insurance family, and I believe that it will be worth our while to spend a few minutes in trying to ascertain the

* Read before the Fourth District Branch of the Medical Society of the State of New York, Plattsburg, Nov. 18, 1919.

reasons why sickness insurance requires compulsion, 50 per cent. subsidies, and various other tonics to make it a going proposition.

In this world of ours the difference between a good and a bad bargain is usually determined by the returns one gets for the money spent; and in the ultimate analysis, insurance is not an exception to this general rule. The economic value of insurance is determined by the magnitude of the risk assumed and by the expected frequency of the event against which the insurance is carried.

Insurance against death is a typical example of insurance of unquestioned economic value. The death of the head of the family is an irreparable damage. The chances of this occurring in any given unit of time are small. For instance, between the years 20 and 42 the risk for any one year is less than 1 in 100. Term life insurance during the years of the average man's economic activity costs only about \$1 a year for each \$100 of protection.

Fire insurance is more universal than life insurance, and this is because from a purely economic point of view it is even more valuable than life insurance. In fire insurance the ratio between cost and protection is for the average risk about \$1 premium per annum for \$600 worth of protection.

Marine insurance is another form of universally recognized insurance. It is not necessary to go into the question of marine insurance rates, but it will be of interest to note that during the palmiest days of the Hun submarine when marine insurance was considered to have become almost prohibitive, the rates for this form of insurance were actually only one-quarter that which is normally necessary to charge in the case of the best risks insured under health insurance.

SICKNESS INSURANCE

The moment we turn to sickness insurance we find conditions absolutely different from those encountered in fire and life insurance. Death occurs but once in the experience of the insured, fires are rare, and the destruction is in most cases total. Sickness, however, is almost a regular incident in the life of a family.

The economic value of insurance decreases as the occurrence against which the insurance is carried becomes more frequent and the distribution more uniform. To illustrate this, suppose that each individual could count on being sick once a year. Then it would be the height of folly to attempt to carry yearly term sickness insurance because, from the very nature of things, the returns from this insurance could only be the amount of the premiums paid less the overhead costs of conducting the insurance. Stripped of superfluous detail, this is the insurance problem actually encountered by the so-called model bill of the American Association for Labor Legislation. The Illinois report shows that out of 215 families investigated by the Bureau of Labor Statistics, 212 had sickness during the year. It is therefore, I believe, self-evident that if the expectation of sickness in the average American working man's family is to be in the neighborhood of 98 per cent. per annum, there is then no question but that as a strict business proposition it would be better for each family to become its own insurer and thereby save the overhead expenses which are unavoidable with all forms of insurance.

At this point it might be well to note the fact that by far the best family health insurance policy yet devised is obtained by setting aside a certain portion of the family income as a savings bank account. The savings bank family health insurance policy is 104 per cent. efficient as compared with the 60 or 70 per cent. efficiency of the best private company sickness insurance and an estimated possible efficiency of about 85 per cent. for state controlled compulsory insurance.

If we dismiss the universal health insurance of the type proposed in the so-called model bills and turn our attention to the limited wage-earner type of compulsory health insurance as illustrated in such bills as the Davenport bill, we are at once confronted by certain definite facts. The chance of the individual worker's becoming sick during the year is not 1:100, or even 1:50, but, as shown by the Illinois report and other studies, approximately 1:5. This fact itself makes straight sickness insurance a very costly proposition. In fact, the ratio between cost and possible benefit is such as to make it scarcely an insurance question at all. The normal cost of insurance covering only loss of wages must, of necessity, be at a rate which makes it almost prohibitive and, I believe, scarcely justifiable as an insurance proposition in any but special circumstances.

For purposes of study we can take one of the best sickness insurance policies ever offered, which is that of the General Electric Mutual Benefit Association of the Schenectady works. The company contributes the overhead costs of maintaining this insurance. During the past six years the policy holders of this association who have been sick have received an average benefit of \$18.54, and the average premium paid has been \$3.83, which gives a ratio of premium to expected benefit of \$1 premium to \$4.84 benefit, with a maximum possible protection of \$21.94 for each dollar paid as premium.

Owing to the fact that the compulsory insurance of the Davenport bill type covers different periods of sickness and loads a large share of the expense on the first week of illness, it can be readily shown that had the 5,276 who have received sick benefits under the General Electric Mutual Benefit Association been insured under the Davenport bill, they would have received only \$2.24 in benefits for each dollar paid as premium. Even with the company paying one half of the premium the ratio would still be \$4.84 for the General Electric Mutual against only about \$4.48 for compulsory insurance. Any trade by which the working man of Schenectady gives up even a fraction of his present liberty for a return of a loss of 36 cents in benefits for each dollar paid for health insurance seems too preposterous for serious consideration.

EXCESSIVE COST OF COMPULSORY HEALTH INSURANCE

The question of excessive cost is really the root of practically all the difficulties encountered by the compulsory health insurance advocates. By excessive cost I do not mean that the total would be beyond the reach of the American working man if he were offered a really good value for the money spent. I have heard it said that compulsory health insurance will cost only from 2 to 4 per cent. of the workman's income. Figured on the \$12 a week basis of the Davenport bill, the benefits could cost not less than 7 per cent. of the \$12 a week wage; but this is entirely beside the question. The really important thing is that the insurance is itself so costly in proportion to the benefits that it is not a good buy for the working man. Consequently, for the workman himself to be compelled to pay for state controlled sickness insurance giving the benefits promised by the Davenport bill, or similar bills, is entirely out of the question. The American working man simply would not submit to any such form of compulsion. His business instincts are entirely too good.

The question of costs at once forced the compulsory health insurance advocates to some sort of subterfuge, and the scheme adopted is to attempt to bribe the working man by some sort of promise of something for nothing. In the case of the Davenport bill, this takes the form of compelling the employer to pay one half or more of the costs of the so-called insurance. To beguile the working man into accepting the

compulsion part of the program, even this promise of half for nothing is not sufficient, and the Committee on Health of the New York State Federation of Labor has adopted a policy of claiming that the total expenses for administering the benefits of the law will be only about one half what they must of necessity be if the benefits are actually to be given to the insured.

History is a long, long story; and in this story the policy of something for nothing has been tried many, many times always with the same results. Is there any reason to expect a different result when it is tried in the guise of compulsory health insurance?

THE PARTIES INVOLVED

There are really four parties directly interested in the compulsory health insurance proposition. They are the working man, the public, the employer and the medical and allied professions.

The working man is to get the something for nothing. The public is represented by the voters, and it is from the very first self-evident that it is useless to ask politicians to compel the public to pay the something which is to be given for nothing. The state might be induced to contribute a small part, but I am certain that every man in this audience will agree with me when I say that the proposition to make the public pay half of the cash and other benefits promised by such bills as the Davenport bill is too preposterous for serious consideration.

We still have two parties left, and the compulsory health bills do actually claim to select the employer to serve in the rôle of the something for nothing contributor.

The compulsory health insurance advocates tell us that compelling the employer to pay for health insurance is only a natural step from the principles of the compensation legislation. This is not true, because the compensation legislation compels industry to pay only for the direct damage done by industry. In order for compulsory health insurance of the Davenport bill type to give fundamental justice at least approximately one half of sickness must be due to industry. In this world of ours it is best to recognize facts as they are; and in this case the fact is that industry cannot properly be charged with one one-hundredth part of ordinary sickness.

The meaning of all this is self-evident. The so-called compulsory health insurance is not health insurance at all, but only a thinly veiled scheme for forcing charity on a portion of the community which neither requires nor desires charity. At the same time the people who ordinarily need charity—those chronically ill, the unemployed, the aged, the widow, the orphans—are not provided for at all. In fact, they will be much worse off; for the available resources of the community will have been used up in forcing charity on the man with the job. I believe that history will fail to show a single example of a law forcing charity on employed working men which has not worked out to the detriment of the working man and served ultimately to enslave him.

CONTROL BY EMPLOYERS

I wish now to call attention to another inevitable difficulty which was bound to confront the compulsory health insurance advocates the minute they undertook to finance, by means of a subterfuge, a scheme which could not stand on its own feet. The very minute you find a bill that says that the employer must pay one half or more of the costs of a measure you can be assured that somewhere in that bill you will find provisions giving the employer one half or more of the control of the machinery which will work the measure. This is so of the Davenport bill and will be so of all bills depending on an employer subsidy to furnish the something for nothing. It is the inevitable price that must be paid for the deception; and from what I know of employers I

am perfectly certain that in the long run the employer will find some way of getting his money back with interest and that the price to be paid by the workman for this something for nothing will be actually greater, or I might say worse, than if the whole transaction were strictly honest from the beginning.

If we turn to the Davenport bill we find in Article 1, Section 3, exempted from the workings of the bill, "all those employees for whose benefit an employer, in the judgment of the industrial commission, maintains at his own cost and without resource to insurance, a system, fund, or plan, which guarantees to such employees benefits substantially the same as benefits they would receive if insured under the provisions of this system." Does any one here believe that this would mean health insurance? No, it would mean that our larger companies would be forced by the exigencies of the law to return to the long ago discarded plan of the company doctor with all the evils and dissatisfaction attendant thereon.

The company doctor is an old plan. We do not have to repeat history with this experiment, which has never been able to survive in this country, except in frontier camps and localities not yet adequately supplied with independent physicians.

The so-called Health Committee of the New York State Federation of Labor claims that ample provision is made for the democratic control of all locals by the employee members; but in Article 4, Section 60, of the Davenport bill we find that "each employer member shall have as many votes for representatives of employers on the board of directors as he employs workmen who are employee members of such fund." Also in Section 55 we find that the boards of directors shall consist of "not more than seven directors which shall consist of an equal number of directors representing employee members, and an equal number representing employer members, and one director in addition." It is not difficult to predict in advance who would really control these boards.

The remaining party that will inevitably be compelled to contribute liberally to the something for nothing, namely, the medical profession, is not represented on the boards at all. There has been considerable talk about minimum provisions to insure adequate protection for the medical profession, but in my opinion the ultimate fate of the medical profession will be determined not by any little details of amendments, but by the great underlying structure on which the legislation is based. Just as long as the entire structure of compulsory health insurance is built on a deception and a false promise of something for nothing, then unless history reverses itself and human nature changes, the medical profession will find itself called on to support the very foundations of a structure which from its birth was destined to be incapable of supporting itself. No possible good can come to the medical profession from getting mixed up in a scheme which from the very start is little else than a dishonest subterfuge.

CONCLUSION

The fact should be emphasized that the moment we are forced to admit that the burden of compulsory health insurance cannot be borne by the insured, then the problem automatically becomes one more related to charity than to insurance. By no stretch of the imagination can the machinery proposed for compulsory health insurance be conceived of as an efficient method for the distribution of charity. The great political army of directors, secretaries, clerks, inspectors and others who would be called into being by compulsory health insurance is entirely too inefficient and expensive a proposition to be substituted for our present scientific development of state medicine and management of the charity problem.

511 State Street.

Miscellany

LEON DAUDET AND HIS RECOLLECTIONS OF HIS MEDICAL COLLEGE

Among the deputies elected to the French chamber in November was Léon Daudet, who has written considerably on medicine in general, on the medical profession and, more particularly, on the celebrated physicians of Paris.

Daudet is a son of the noted author, Alphonse Daudet. Although Léon Daudet, the son, also has become an author, he was originally destined for the medical profession. For seven years he pursued his medical studies at the Paris Faculty of Medicine and passed all his examinations but did not support a thesis, which is an indispensable requirement for the degree of doctor of medicine. He had even been appointed, first extern and then provisional intern, at the Hôpitaux de Paris, but he did not achieve the full title of intern. He soon after broke off his relations with the Faculty of Medicine, and in 1894 he published a book, the mere title of which gives an insight into the mentality of its author. The title of his book was, "Les Morticoles" (The Morticulturists), that is, cultivators of death. This pamphlet was directed against the professors of the Paris Faculty of Medicine. The statement has been made that in this pamphlet, breathing violence and rudeness, as it does, Léon Daudet has given vent to the malice he entertained toward some of his former teachers who had not shown him all the consideration to which he felt he was entitled. Be that as it may, Daudet has recently called up his memories of his period of medical study in an interesting and more carefully prepared volume entitled, "Devant la douleur" (In the Face of Pain), in which the silhouettes of a great number of savants and well known physicians and surgeons pass in review, many of whom are no longer of this world: Charcot, Brouardel, who was a former dean of the Paris Faculty of Medicine; Bouchard, Brissaud, Potain, the great heart specialist; the surgeons Tillaux, Richet (father of the physiologist, Charles Richet), Lucas-Championnière, Péan, Doyen; the famous syphilologist, Alfred Fournier; the anatomists, Farabeuf and Poirier; the gynecologist, Pozzi; the embryologist and histologist, Mathias Duval; the military surgeons Kelsch and Villemin, and others. A number of living colleagues are also mentioned, among whom are Babinski and Professors Debove, Charles Richet and Albert Robin.

It is true that Daudet's recent book, also, is full of the exaggerations and the violent language that characterize the pamphleteer, and a number of the character sketches that he draws are in reality only caricatures; for example, when he refers to Péan beginning his day's work in the operating room: "The skilled wielder of the scalpel cuts off three legs, two arms, disarticulates two shoulders, trephines five skulls, removes as if it were child's play half a dozen uteri together with the adnexa, and takes out several pairs of ovaries. . . . At the end of two hours of this exercise he was dripping with blood and sweat. His hands, or, I should say, his paws, were as red as those of an assassin; his feet were soaked in life's red stream; yet, withal, he was as merry as a marriage bell. And why not? Had he not performed his function here below—to cut, to open, to resect, to bone and to eviscerate?" However, as in all caricatures, a certain basic truth can be discovered. It wasn't for naught that the students had nicknamed Péan "*le père coupe-toujours*" (Father Everet Cutting), and the regretted Professor Grasset once told me of having been present at one of these operative sittings, at which, on inquiring of Péan what his diagnosis was in the case of the patient who was about to be operated on, received from him the reply: "That is just what we are going to find out by opening the abdomen."

The critics have been very unjust to Léon Daudet in stating that he has ridiculed all the French representatives of the medical profession. Far from it. Daudet speaks in respectful, even affectionate, terms of Villemin, justly celebrated for his work on the contagiousness of tuberculosis.

He refers to him as "a scholar possessing an admirable character in every respect." Of Professor Kelsch he says: "He combined with an irresistible medical instinct the highest scientific culture." Tillaux, the surgeon, he thinks, possessed "excellent heart qualities; was a sure practitioner and a man of unquestionable integrity." Farabeuf, the anatomist, was gifted with "genius and the power of exposition;" "was devoted to his work and to science in general;" was not open to flattery, and shunned all corrupt practices and intrigue; "rarely did ever a man despise more than he money and conventional honors." Daudet also seems to have carried away with him an exalted recollection of the service of Lucas-Championnière at the Hôtel-Dieu Hospital. This surgeon was the first in Paris to apply rigorously antiseptic and aseptic surgery. He operated without haste, always showing himself very considerate "of the limbs and tissues of his patients." Of Mathias Duval, professor of embryology, he says: "He was a very clear lecturer. One always had the feeling that he had left nothing unsaid that should have been said. His history of the development of the human ovum was most admirable." As regards character, he gave one the feeling of serenity combined with force, of possessing "a loftiness of spirit that held him aloof from corrupt practices and faculty intrigues, and caused him to flee from the clatter of voices and the bestowal of praise. . . . He was one of the most beautiful and noble characters that France has produced in the field of science."

But Professor Potain comes in for an even greater share of Daudet's admiration; in fact, his book, *Devant la douleur*, is dedicated "to the exalted memory" of Potain. Daudet enjoyed the privilege of knowing the celebrated clinician very intimately. "Providence," he says, "afforded me for several years the opportunity of direct contact with this great teacher, and allowed me to listen reverently to his advice and counsel." As a clinician he was extremely resolute. He spoke and acted like a man who had a sense of his own true worth. When called at the same time as Charcot to the bedside of Alphonse Daudet, who was suffering from a severe bronchitis, he recommenced the auscultation that his illustrious colleague had just finished without paying any attention to Charcot's remark: "But I have just finished— . . ." "Nowhere could one learn the pathology of the heart and the blood vessels, the premonitory signs of tuberculosis and of interstitial nephritis as one could in his class room. It was interesting to see him perform auscultation. He would listen long and intently at one spot; would wait some time and then begin again. . . . Not a murmur, nor a purr, not a triple sound, though never so slight, escaped him. His hearing was not outclassed even by Cooper's Indians." He was also a man of great kindness of heart, which inured to the benefit of his surroundings. On one occasion a convalescent patient, who was in very straitened circumstances, was preparing to leave Potain's service. Just as he was leaving, Potain slipped a 500 franc note in his hand, and having done so Potain beat a hasty retreat, as if guilty of theft, not waiting to hear the man's expressions of gratitude.

Daudet knew intimately also Professor Charcot, who was a friend of his father, Alphonse Daudet. He pays homage to the sagacity of the clinician, and praises his immense erudition and his genius as an observer. Charcot was an indefatigable worker who spent at times a great part of the night studying into some problem pertaining to pathologic anatomy, or in working out the details of some schema, such as his famous graphic representation of the diverse forms of aphasia. But—quite the contrary of Potain, all of whose intellectual forces were directed toward the alleviation of pain—Charcot seemed to assume a disdainful attitude toward therapeutics in general. "He considered the disorders of the human machine much as an astronomer views the movements of the stars." He was very dictatorial and could not endure contradiction. According to Daudet, whenever he thought that any one had presumed to contest any of his medical doctrines with respect to hysteria major, aphasia, multiple sclerosis, etc., he became furious and violent. The situation in which those studying under him found

themselves was not exactly comfortable. A certain amount of initiative, and a certain amount of originality, even, he would accord them, provided their initiative and their originality did not clash with the opinions and theories of the master. Any derogatory references to the doctrines that he had established were considered rank treason and were punished as such.

A NEW PRESERVATIVE FOR CADAVERS

The introduction of phenol (carbolic acid) in 1864 as a preservative for anatomic material, followed by glycerol in 1867 and by formaldehyd in 1890, revolutionized research in anatomy. The miracle wrought by these and other chemicals in rendering the dissecting room relatively odorless has been of incalculable comfort to students and teachers. However, none of these substances is ideal, and anatomists have continually sought for a substance which would not only preserve the delicate tissues without the production of odor, and be nontoxic and nonvolatile, but also be inexpensive, and not require renewal. Experiments recently reported by Myer (*Science*, Dec. 19, 1919, p. 570) appear to indicate that liquid petrolatum may be utilized as a preservative for cadavers. It extracts practically nothing from the tissues. It softens and later protects the epidermis which, after thorough impregnation with the substance, resists drying much better than if other preservatives had been used; and the eyelids, nose, digits, lips, ears and genitalia do not require such careful protection during dissection. Material stored in petrolatum for more than two years is practically odorless, and appears to be in identically the same condition as when immersed. On removal, the material need drain only a few minutes when it is ready for wrapping. The specific gravity of the oil is low, so that bodies readily sink in it. Inspection of the material in the tanks is easy. So long as there is sufficient oil in the tanks, all material is hermetically sealed and there is no subsequent loss from evaporation. The initial cost of the oil is not large and, since it can be used over and over, its use ultimately is economical. Fire risks are negligible. Phenol may be added to the oil if desired, although there appears to be no necessity for it.

HEALTH AS A DISEASE

"Avoid extremes" says an ancient proverb. The following editorial from the Gary (Ind.) *Times* applies the saying to the health faddist:

There is a great deal of truth in the satirical story of Jiggins, who had the health habit. Jiggins lived twenty years ago, and health was a disease with him. The *Dallas News* says that Jiggins took a cold plunge every morning. He said it opened his pores. After it he took a hot sponge. He said it closed the pores. He got so that he could open and shut his pores at will.

Jiggins used to stand and breathe at an open window for half an hour before dressing. He said it expanded his lungs. He might, of course, have had it done in a shoe shop with a boot stretcher; but, after all it cost him nothing this way. And what is half an hour?

After he had got his vest on, Jiggins used to hitch himself up like a dog in harness and do shadow exercises. He did them forward, backward and hind-side up.

He could have got a job as a dog anywhere. He spent all his time at this kind of thing. In his spare time at the office he used to lie on his stomach on the floor and see if he could lift himself up with his knuckles. If he could, then he tried some other way until he found one that he couldn't do. Then he would spend the rest of his lunch hour on his stomach, perfectly happy.

In the evenings, in his room, he used to lift iron bars, cannon balls, heavy dumb bells and haul himself up to the ceiling with his teeth.

He liked it.

He spent half the night slinging himself around his room. He said it made his brain clear. When he got his brain perfectly clear he went to bed and slept. As soon as he awoke he began clearing it again.

Jiggins is dead. He was, of course, a pioneer; but the fact that he dumbelled himself to death at an early age does not prevent a whole generation of young men from following in his path.

They are ridden by the health mania.

They make themselves a nuisance.

They get up at impossible hours. They go out in silly little suits and run marathon heats before breakfast. They chase around barefoot to get the dew on their feet. They hunt for ozone. They bother about pepsin. They won't eat meat because it has too much nitrogen. They won't eat fruit because it hasn't got any. They prefer albumin and starch to huckleberry pie and doughnuts. They won't drink water out of a tap. They won't eat sardines out of a tin. They won't use oysters out of a pail. They won't drink milk out of a glass. They are afraid. Yes, sir, afraid. Cowards!

And after all their fuss they presently incur some simple, old-fashioned illness, and die like anybody else.

Book Notices

ORGANIZATION OF PUBLIC HEALTH NURSING. By Annie M. Brainard. Cloth. Price \$1.35. Pp. 144 with 11 illustrations. New York: Macmillan Company, 1919.

This, the first handbook of a contemplated series on the subject, bears the endorsement of the National Organization for Public Health Nursing. Written by a lay woman, the work gives a clear insight into organization and executive requirements for efficient efforts in its field. In addition to the presentation of general principles, special details and statistical data gained from experience are introduced. The scope of the manual is indicated in the table of contents: the need of organization; fundamental principles; forms of organization; the nurses' part in organizing; organizing public health nursing in a new community; boards of directors; committee on finance; committee on nurses; the supply committee; records and statistics; reorganization. The term "public health nurse" is defined as a generic term including district nurses, school nurses, factory nurses, tuberculosis nurses, child welfare nurses, and all nurses engaged in social or settlement work as distinguished from private duty or institutional nurses.

TEACHING THE SICK. A Manual of Occupational Therapy and Re-Education. By George Edward Barton, A.I.A., Director of Consohation House. Cloth. Price, \$1.50. Pp. 163 with illustrations. Philadelphia: W. B. Saunders Company, 1919.

The lessons conveyed in this concise handbook were learned in the school of experience. The author is "self made," for earlier in life he won a victory over his own physical handicaps. No attempt has been made to produce a textbook on the reeducation of military and industrial cripples; the manual discusses broad principles, and special methods which may serve as illustrations. The modest desire is apparent to dispel prevalent misconceptions fostered by amateur enthusiasts, for in the mind of the author, occupational therapy presents two sides: one, education; the other and more important, therapeutics. It is not sufficient, then, that one be a craft teacher; one should have experience with pain, sickness and disability to qualify as a competent "occupational therapist." The treatise is worth reading for its good advice and many helpful hints.

LA TRICOMONOSIS INTESITAL. Por el Dr. Edmundo Escobel, Delegado de la Facultad de Medicina, Paris. Paper. 1p. 78, with illustrations. Lima: Saumarti y Ca, 1919.

The author began his study of trichomoniasis in 1898. Recently he received a prize from the Academy of Medicine of Paris for this work. In this pamphlet he summarizes the history, distribution, pathogenicity, etiology, pathology, diagnosis, prognosis, clinical course and treatment of the disease. He claims to have demonstrated that the infecting organism *Trichomonas intestinalis*, is pathogenic not only in the intestine but also in the vagina and gums, producing disorders which can be cured only after these organs have been treated with iodine.

Medicolegal

Parent Not Providing Medical Attention for Child

(*State v. Barnes (Tenn.)*, 212 S. W. R. 100)

The Supreme Court of Tennessee reverses the judgment of the trial court and remands for further proceedings this case in which the trial court quashed an indictment which charged that the defendant unlawfully, wilfully and without good cause neglected and failed to provide for an infant child under the age of 16 years, according to his means, by suffering the child to sicken and die without proper treatment and medical attention. The supreme court says that it is the legal duty of the father to provide proper care, treatment, and medical attention for his child. If by reason of his breach of this duty the death of this child resulted, the father may be guilty of homicide. If one owes to another a plain particular and personal duty, imposed either by law or by contract, an omission, resulting in the death of the party to whom such duty was owing, usually renders the delinquent party guilty of a homicide. This proposition is very well established by authority. And this principle has been applied in cases of the neglect of the duty of a parent to care for his child, and to provide medical attention. As to whether a parent so neglecting his child is guilty of murder or of manslaughter would depend on the circumstances. If the neglect be wilful or malicious, it is probably a case of murder. If the omission is not malicious, and is a mere case of negligence, the parent is perhaps guilty only of manslaughter.

Power to Require Blood Test of Milk Dealers

(*People ex rel. Schultz v. Hamilton, Commissioner of Public Safety, et al. (N. Y.)*, 177 N. Y. Supp. 222)

The Supreme Court of New York, Appellate Division, Fourth Department, reverses an order that denied the relator's motion for a writ of mandamus to compel the issuance to him of a license to sell milk in the city of Rochester, which he had been refused because he declined to submit to a blood test for the purpose of determining whether or not he had ever had typhoid fever or was a carrier of typhoid germs. His application for a license was made first to the health officer of the city, and, secondly, to the commissioner of public safety. The court says that it might be assumed that the regulation for a blood test was not harsh or unreasonable, that it was salutary, and that either the legislature or the common council, by appropriate enactments, could make such a provision applicable generally to milk dealers in the city. In fact, the relator so expressly conceded, and admitted that, if such an enactment did exist, by either the legislature or the common council, he would have no remedy. But neither the legislature nor the common council had so enacted. The sole statutory requirement for lawful trafficking in milk and cream in the city was the possession of a license issued by the health bureau of the department of public safety of the city. The regulation was one devised by either the health officer or the commissioner of public safety. The local health officers were the commissioner of public safety, as head of the department of public safety, and, under him, the health officer; but the power to make general orders and regulations for the preservation of life and health and the execution of the public health law was vested in the common council of the city. That the regulation sought to be maintained for a blood test was one of general application could not be doubted. It was not aimed at the suppression of a nuisance, nor to meet any emergency situation. There was no typhoid epidemic, present or imminent. There was no special reason for believing that the relator either had typhoid or was a carrier of typhoid germs. This case seemed, therefore, to fall squarely within the provisions of the statute, requiring legislation by either the legislature or the common council to be effective. Quite evidently the scheme of all the legislation was to require the concerted action and judgment of more than one individual as a prerequisite to general regulatory measures, leav-

ing in the commissioner and the health officer a discretion only in the manner of applying in detail those general regulations. The commissioner and health officer were administrative officials. They had no power to legislate. They might determine facts and conditions which made applicable the general regulations, and might even prescribe regulations for carrying into effect the general enactments of the appropriate legislative bodies. The discretionary power vested in these officers by the city charter to grant or withhold licenses related only to the limited powers of those officers as defined above, and did not create in them a legislative discretion. However salutary and desirable this particular regulation might be, it could not be given force and effect until the appropriate legislative body had enacted it in a lawful manner. That power so to enact had not been and could not be delegated.

Descriptive Terms and Evidence in Abortion Case

(*State v. Patterson et al. (Kan.)*, 181 Pac. R. 609)

The Supreme Court of Kansas affirms a judgment of conviction of the two defendants, physicians, who were convicted of manslaughter in the fourth and first degrees, respectively, the charge against them being that they had operated on a named woman to produce an abortion, thereby causing her death, while they asserted that the purpose of the operation was to remedy conditions brought about by a venereal disease from which she was suffering, and that she was not pregnant. The court says that complaint was made of a failure of the trial court to give an instruction to the jury under the section of the statute making it manslaughter in the second degree to administer a drug to a woman "pregnant with a quick child" with intent to destroy it, or to employ an instrument with that purpose, when the death of the child or mother resulted therefrom. But such an instruction would not have been proper under the information, which did not charge that the woman was "pregnant with a quick child," but alleged that she was "pregnant with vitalized embryo." The latter expression was not equivalent to that of the statute referred to. "Vitalized," merely means endowed with life. Any human embryo which is not dead is "vitalized." It is no less endowed with life before reaching the stage of development known as quickening than after. A woman is said to be pregnant with a quick child, or quick with child, when the motion of the fetus becomes perceptible, usually about the middle of the period of pregnancy. Not only was this condition not pleaded; it was not indicated by the evidence.

At a postmortem examination of the body of the woman, conducted by the defendants, the uterus was removed and placed in a jar of alcohol. At the trial they produced what they represented to be the same jar and contents, together with evidence that its appearance showed that the uterus was not that of a woman who had been pregnant. The court told the jury in substance that in order for the testimony of experts concerning the appearance of the uterus to have weight with them, they must first find from the evidence that no substitution had been made, that the organ produced was the one taken from the body, and that it had not been tampered with, but had been exhibited to the witnesses in the same condition as when first removed. This instruction was complained of, not as involving any incorrect statement of a principle of law, but as objectionable because it singled out for comment one particular feature of the testimony, and suggested to the jury that the court itself suspected substitution or alteration. But, granting that the specific reference to the question of the genuineness of the exhibit was open to the objection stated, it would not in itself justify a reversal of the judgment.

Several witnesses were permitted to testify that the woman had told them that she was pregnant, and was going to one of the defendants for an operation on that account. This evidence was objected to as incompetent, as being pure hearsay. But it has often been said by courts and text-writers that such testimony is admissible. Moreover, whether or not it was technically competent, the admission of evidence that the subject of the operation, who died as a result of it, had

stated that she was pregnant and was going to see the defendants on that account, was nonprejudicial because not inconsistent with the defense made, when the defendant's own version of the affair was that while the woman was really suffering from gonorrhea, and knew it, she had led her mother and neighbors to believe that she was pregnant, and that she was going to see the defendants on that account, her purpose being to conceal the fact that she had a venereal disease.

Evidence and Timeliness in Action for Malpractice

(*Perkins v. Trueblood* (Calif.), 181 Pac. R. 642)

The Supreme Court of California, in reversing a judgment that was rendered in favor of the plaintiff, and remanding the case for a new trial, says that the court below tried the case without a jury, and made its findings in favor of the plaintiff, which in substance were that the plaintiff broke his leg in March, 1912; that the defendant was employed to reduce the fracture; that the fracture not satisfactorily healing, the defendant separated the surfaces of the bone during the month of April, 1912, and again set the plaintiff's leg; that the defendant performed the latter operation negligently; and that by reason of this the plaintiff had suffered damage in the sum of \$1,250. The defendant's appeal presented the question of the sufficiency of the evidence to support the findings and also the question of the correctness of rulings admitting evidence concerning the plaintiff's condition and the defendant's surgical treatment of him prior to April 9, 1912. While the court's findings rested the plaintiff's cause of action on the defendant's negligent resetting of the plaintiff's leg in April, 1912, nevertheless it would seem that the trial court proceeded on the theory, and correctly so, that the negligence ultimately found against the defendant was dependent in a measure on the condition of the plaintiff's leg at the time of and subsequent to the setting of the original fracture, which occurred in March, 1912. On this theory, evidence relative to the original fracture, its treatment and progress, and process of its healing, was admissible, to the end that it might be determined whether or not the methods resorted to by the defendant in resetting the leg on or after April 9, 1912, were of a nature which an ordinarily skilful surgeon would have given to a leg in such a condition.

Furthermore, this being the theory of the case and the judgment, it followed that there was no merit in the contention that the commencement of the action, wherein the complaint was filed on April 9, 1913, was barred by Subdivision 3 of Section 340 of the Code of Civil Procedure, requiring such actions to be commenced within one year.

Attention is called to the fact that, in spite of the great suffering and financial loss claimed to have been endured by the plaintiff for a period of ten months following the last treatment by the defendant, it affirmatively appeared that the defendant was not requested to give any further treatment, and that the plaintiff failed to place himself under the care of any other surgeon. Moreover, with regard to the fracturing again of the same leg in the same place, when, as the plaintiff testified, he did not fall over 12 inches, and there was no evidence of any circumstance preceding or attending the fall, the supreme court thinks that, in view of the fact that a person may snap a perfectly sound leg in a fall of 12 inches or less, the claim that the defendant's negligence was the proximate cause of the second fracture, found, to say the least, very slight support from the facts revealed by the record; and, on this analysis of the case, the supreme court finds it difficult to consider seriously the claims advanced by the plaintiff.

There was some evidence which tended to show that at the time of the fall and the second fracture the ends of the broken bone overlapped nearly one-half inch, and that there was no complete bony union prior to the treatment by another physician for the final fracture resulting from the fall. In the absence, however, of a showing that such a condition would have been at least improbable, had the leg received reasonably prudent and ordinarily skilful surgical treatment, it could not be said that the mere pathologic con-

dition of the leg in and of itself sufficed to show negligence on the part of the defendant in resetting the leg. In the absence of evidence, it could not be assumed that he proceeded, if he proceeded at all, without ordinary care or skill.

Violation by Physician of Speed Law

(*People v. Seidler* (N. Y.), 176 N. Y. Supp. 677)

The Kings County, N. Y., court, in affirming a judgment of conviction, and of sentence of the defendant to a term of ten days in the county jail, for violation of the speed law, says that the defendant was a practicing physician, who admitted that he was operating his automobile at a rate of speed much in excess of the limit permitted by law, and on the hearing before the magistrate offered one excuse in extenuation of his act, and in this court submitted a different one. After the consequences of his act were forcibly impressed on him by his sentence, it was an easy matter for him to resort to the means which are available to a physician; but such carefully considered claims thus offered could have but little weight on this appeal. Were this his first violation of the speed law, an entirely different situation would present itself; but on five prior occasions he was arrested for similar violations in various parts of the city and by different officers. A physician has no rights on our highways superior to that of any other motorist. The law is no respecter of persons, and all must bow in obedience to it, and he who violates it does so at his peril. We can, however, readily understand that emergencies may occasionally confront a physician who may be called in a "life or death" case, wherein his haste to give relief can be partially excused or entirely overlooked. Such excuse, being ever present in the mind of a physician, may readily be used as a subterfuge to defeat the ends of justice. In this respect, reliance on the value of such form of defense must be placed on the magistrate hearing the evidence, who is in a position to gage properly its dependability. On the hearing in this case, the statements made by the defendant but vainly suggested extenuating circumstances, and the court properly disregarded them.

Society Proceedings

SOUTHERN MINNESOTA MEDICAL ASSOCIATION

Annual Meeting, held in Mankato, Dec. 1 and 2, 1919

DR. AARON F. SCHMITT, Mankato, in the Chair

Surgical Treatment of Bunions

DR. C. H. MAYO, Rochester: Several methods of treatment are resorted to according to the conditions present. The usual operation performed is one which I advocated many years ago. A curved incision is made convexly upward over the inner side of the joint. The skin is deflected downward, the bunion bursa is dissected forward and the joint is opened, the bursa being left attached to the inner surface of the first phalanx. One-quarter inch of the head of the articulating surface is removed by bone saw or large bone-biting forceps. This relaxes the extensor and the flexor tendons. The bony projection on the inner side of the head of the great toe is removed, and the bunion bursa is turned into the joint and held by sutures of catgut which also serve to straighten the great toe, thus removing the valgus. The wound is closed without drainage. If flatfoot complicates, the head of the bone should be preserved. The bunion bursa, the overgrowth of bone and the sesamoid bones should be removed, however. If the hallux valgus is marked, the tendon of the extensor hallucis longus should be lengthened about one-fourth inch. If the great toe is bent downward, the sesamoid bones can be removed with a knife or sharp pointed scissors, if they are grasped with strong tenaculum forceps. The sesamoid bones and the articulating surface should not be removed from the same foot. The patients should be up at the end of the first week, using the heel and outer side of the foot. In from fourteen to twenty-one days, a stiff soled shoe may

be worn. Instructions should be given to every patient as to the size and shape of shoes to be worn following operation.

Treatment of Second Stage of Labor, with Special Reference to Prevention of Injury to Child and to Pelvic Floor

DR. JOSEPH B. DE LEE, Chicago: Watchful expectancy and natural delivery will give the best results in the conditions in which the vast majority of births occur. The indiscriminate use of forceps, of pituitary solution and of forced delivery will do immeasurable harm. In primiparas and in multiparas, with rigid pelvic floor, I shorten the second stage artificially. When the head has reached the pelvic floor and the levator ani muscles have begun to stretch, I consider the advisability of interference. If the pains are strong, a few extra whiffs of ether or gas are given, and a deep episiotomy is made. The patient will then deliver herself; or if the pains lag, two or three drops of pituitary solution are given. Perineotomy is one of the most important parts of the prophylactic forceps, because it is intended to preserve the integrity of the pelvic floor, the subvesical fascia, and the urogenital septum; at the same time it prevents injury to the child's brain. The prophylactic forceps operation is a radical departure from time honored custom, but it has a sound scientific basis for recommendation. It also saves the woman the physical labor of a prolonged second stage. By relieving pressure on the child's brain, the occurrence of idiocy, epilepsy, etc., is lessened. Prophylactic forceps also prevent asphyxia, both in its immediate effects and its remote influence on the early life of the infant.

Intrathoracic Goiter

DR. E. S. Judd, Rochester: Intrathoracic goiter is one in which the greater part of the thyroid enlargement is situated within the thorax. Substernal goiter is one in which there is a projection of only a part of the thyroid into the chest. This type occurs in nearly 50 per cent. of the goiters coming to operation, while the intrathoracic type occurs in only 5 per cent. Histologically, the intrathoracic goiter is an adenoma, associated in many cases with colloid or carcinoma. The hypertrophied gland of the exophthalmic type is never seen in the totally intrathoracic goiter. There may, however, be a substernal projection from the exophthalmic goiter. The intrathoracic tumor in the benign cases is definitely encapsulated, and can usually be enucleated from its capsule without serious difficulty if the proper treatment is used. The symptoms caused by intrathoracic goiter are mainly the result of pressure on the surrounding viscera. They differ from the symptoms of ordinary cervical goiter only in their intensity. Intrathoracic goiter may be thyrotoxic. The intrathoracic goiter may be recognized by the feeling of a recurring mass when the patient swallows, if pressure is made in the episternal notch with the palpating finger. A finger placed in the pharynx may also make the diagnosis. Ptosis and fixation of the larynx are points in the differential diagnosis. The roentgen ray is of great aid. The operative prognosis is good, except in cases of prolonged toxicosis. The first steps in the operation are the same as in cervical goiter. The thyroid vessels should be divided on one or both sides. The upper pole is then freed. The lateral veins are now divided. Then by making traction on the upper pole, and gradually freeing the intrathoracic part with the finger, the whole lobe may be turned over onto the trachea. If the goiter seems adherent, it may be enucleated by thrusting the finger deep into the adenoma. After the whole gland is lifted into the neck, the inferior thyroid vessels may be handled without difficulty. One should be prepared to perform tracheotomy during and for the first few days following operation. In 150 cases of substernal and intrathoracic goiter occurring at the Mayo Clinic in 1918, the symptoms were of the pressure type. The tumor was on the left side in eighty-one cases, on the right side in forty-five cases, and in the middle portion of the gland in four cases. In sixteen cases, the condition was bilateral. There were 141 adenomas, one hypertrophy associated with adenoma, four carcinomas, and two colloid goiters with small adenoma. Three of the tumors originated from aberrant thyroids.

Acute Perforations of Stomach and Duodenum

DR. N. O. RAMSTAD, Bismarck, N. D.: Perforations of the stomach are more dangerous than those of the duodenum, because of the more infectious character of its contents and the tendency toward general dissemination throughout the abdomen. The prognosis depends mainly on the time which elapses between the rupture and the operation. Undoubtedly, a small number of patients with acute perforation recover temporarily under medical treatment, or the "let alone" plan, but the number is small compared with the recoveries following prompt and efficient operation.

Tuberculids in Recognition of Obscure Tuberculosis

DR. J. H. STOKES, Rochester: While the tuberculous character of tuberculids may be regarded as still open to discussion, the demonstration of their constant association with tuberculosis is now so nearly complete that the occurrence of typical lesions of any one of the various types of tuberculids has a high diagnostic value in the recognition of obscure forms of systemic tuberculous infection. An analysis of a group of patients in the Mayo Clinic has suggested the close association which may exist between erythema nodosum and purpura, and the papulonecrotic tuberculid. The records of the clinic now include a necropsy in a case of erythema nodosum in which death resulted from miliary tuberculosis, and yet no evidence of the existence of any focus of infection other than the tuberculous could be identified. Tuberculids, because of their close association with lymph gland tuberculosis, are often of service in the identification of the tuberculous character of adenopathies, mediastinal glandular enlargements, tuberculosis of the uterine adnexa, etc. The occurrence of a partial positive Wassermann reaction in association with tuberculids, in the apparent absence of syphilis, has been noted. In a study of the diagnostic errors occurring in connection with tuberculids, it was found that only 17 per cent. were diagnosed correctly. Tuberculosis was not suspected from the cutaneous findings in any case; one third of the tuberculids were ignored as being insignificant; two thirds of the mistaken diagnoses were given as syphilis. Syphilis was most often suggested by scars, arthritis and myalgic pains with anemia; one fifth of the patients had sustained needless surgical procedures. The occurrence of false therapeutic effects, due to the action of arsphenamin, in these cases still further increases the possibility of a mistaken diagnosis. The appearance of a tuberculid in an otherwise seemingly healthy individual should be the signal for a searching clinical and roentgenographic examination for a focus of tuberculosis.

Modified Inguinal Hernia Technic

DR. GEORGE EARL, St. Paul: I have never found any functional or anatomic objections to placing the cord completely under the external oblique muscle. This modified technic covers the cord only by the superficial fascia and skin from its exit at the region of the internal ring, but it is covered by nothing else as it goes over the pubic bone, a far more exposed region. There is less liability to strangulation of the cord than when a new external ring is to be formed from the external oblique. Reports from thirty-eight patients operated on show no complaint of pain from the lessened covering, and there have been no recurrences.

Conditions Contraindicating Operation with Stone in Kidney and Ureter

DR. W. F. BRAASCH, Rochester: Probably 75 per cent. of renal stones are passed spontaneously. It is usually inadvisable to operate for stone in either kidney or ureter until at least from three to six months have elapsed since the onset of symptoms. Exceptions to the rule are: excessive and continued pain; evidence of cortical or perinephritic infection, and continued urinary retention; also, if the stone is evidently too large to pass. Conditions permitting the formation of multiple stones are usually surgical. Conditions may be such that operation with bilateral renal lithiasis is definitely contraindicated. Clinical evidence of a low renal function will usually contraindicate operation, when

the symptoms are not very acute or persistent. The operation may be justifiable with acute symptoms, even though the renal function is far below the normal. Removal of stone in the presence of chronic nephritis does not affect the course of the primary nephritis, and unless surgical conditions are urgent, operation is inadvisable. Stones occurring with a bilateral pyelonephritis, however, should be removed even though the symptoms are not urgent. When the opposite kidney is practically functionless or absent, the question arises whether operation on a single kidney or ureter is justifiable. Such operations are frequently done with success. Operation for stone in a polycystic kidney would be justifiable in selected cases. Coincident lesions in other organs are frequently noted. When the several conditions are surgical, that lesion which causes the most acute symptom would naturally necessitate operation first. Hypertrophy of the prostate coincident with renal lithiasis usually takes precedence in regard to operation. Pregnancy, when less than six months, offers no contraindication to operation, and it may be necessary to operate when the symptoms become acute, even in the latter months. As a rule, in the later period of pregnancy, it would be advisable to defer any operation. Attempts to dislodge the stone should not be made in the presence of acute impaction with continued obstruction, acute renal infection, intolerance on the part of the patient to the cystoscope, anatomic deformity, and when the stone is more than 2 cm. in diameter.

Modern Conceptions Regarding Radical Mastoid Operation

DR. HORACE NEWHART, Minneapolis: Every suppurating ear is a menace to the patient. The radical operation or one of its modifications is clinically indicated, with but very few exceptions, in all cases of chronic purulent middle ear discharge which are not permanently cured by persistent conservative treatment, including the removal of all possible causal factors in the nose and nasopharynx.

Surgical Treatment of Gummatous Osteitis of Skull
